(54) Title: **FUSION PROTEIN DELIVERY SYSTEM AND USES THEREOF**

(57) Abstract: The present invention provides a composition of matter, comprising: DNA encoding a viral Vpx protein fused to DNA encoding a protein. In another embodiment of the present invention, there is provided a composition of matter, comprising: DNA encoding a viral Vpr protein fused to DNA encoding a protein. The present invention further provides DNA, vectors and methods for expressing a lentiviral pol gene *in trans*, independent of the lentiviral gag-pol. A gene transduction element is optionally delivered to a lentiviral vector according to the present invention. Also provided are various methods of delivering a virus inhibitory molecule to a target in an animal. Further provided is a pharmaceutical composition.

WO 01/44481 A1

## FUSION PROTEIN DELIVERY SYSTEM AND USES THEREOF

5

## RELATED APPLICATIONS

This patent application is a continuation-in-part of patent application 09/089,900 filed June 3, 1998 which is a continuation-in-part of patent application 08/947,516 filed September 29, 1997, which is a file-wrapper continuation of patent application 08/421,982, all of which are incorporated herein by reference.

10

## FIELD OF THE INVENTION

The present invention relates generally to the fields of molecular virology and protein chemistry. More specifically, the present invention relates to the use of Human and Simian Immunodeficiency Virus (HIV/SIV) Gag proteins, or amino acid residues that mediate their packaging, as vehicles for delivery of proteins/peptides to virions or virus-like particles and uses thereof.

## BACKGROUND OF THE INVENTION

Unlike simple retroviruses, human and simian immunodeficiency viruses (HIV/SIV) encode proteins in addition to Gag, Pol, and Env that are packaged into virus particles. These include the Vpr protein, present in all primate lentiviruses, and the Vpx protein, which is unique to the HIV-2/ SIV<sub>SM</sub>/SIV<sub>MAC</sub> group of viruses. Since Vpr and Vpx are present in infectious virions, they have long been thought to play important roles early in the virus life cycle. Indeed, recent studies of HIV-1 have shown that Vpr has nucleophilic properties and that it facilitates, together with the matrix protein, nuclear transport of the viral preintegration complex in nondividing cells, such as the macrophage. Similarly, Vpx-deficient HIV-2 has been shown to exhibit delayed replication kinetics and to require 2-3 orders of magnitude more virus to produce and maintain a productive infection in peripheral blood mononuclear cells. Thus, both accessory proteins appear to be important for efficient replication and spread of HIV/SIV in primary target cells.

Incorporation of foreign proteins into retrovirus particles has previously been reported by fusion with *gag*. The yeast retrotransposon Tyl was tested as a retrovirus assembly model to interfere with viral replication. (G. Natsoulis et al., *Nature* 1991, 352:632-5). More recently, the expression of a murine retrovirus capsid-staphylococcal nuclease fusion protein was found to inhibit murine leukemia virus replication in tissue culture cells. The expression of Gag-staphylococcal nuclease reduces viral titer and diminishes viral infectivity to promote an anti-HIV strategy. (G. Schumann et al., *J. Virol.* 1996, 70:432937).

Lentiviral vectors, specifically those based on HIV-1, HIV-2 and SIV, have utility in gene therapy, due to their attractive property of stable integration into nondividing cell types (Naldini, L. et al., *Science* 1996, 272:263-267; Stewart, S.A. et al., *J. Virol.* 1997, 71:5579-5592; Zhang, J. et al., *Science* 1993, 259:234-238). The utility of lentiviral-based vector use for human therapy requires the development of a safe lentiviral-based vector. HIV virion associated accessory proteins (Vpr and Vpx) have been shown to be useful as vehicles to deliver protein of both viral and non-viral origin into HIV particles (Liu, H. et al., *J. Virol.* 1995, 69:7630-7638; Liu, H. et al., *J. Virol.* 1997, 71:7704-7710; Wu, X. et al., *J. Virol.* 1994, 68:6161-6169; Wu, X. et al., *EMBO Journal* 1997, 16:5113-5122; Wu, X. et al., *J. Virol.* 1996, 70:3378-3384). We recently demonstrated that trans- RT and IN mimic cis- RT and IN (derived from Gag-Pol). The trans- RT and IN proteins effectively rescue the infectivity and replication of virions derived from RT-IN minus provirus through the complete life cycle (Liu, H. et al., *J. Virol.* 1997, 71:7704-7710; Wu, X. et al., *J. Virol.* 1994, 68:6161-6169). Moreover, these findings demonstrate that truncated Gag-Pol precursor polypeptide (Gag-Pro) support the formation of infectious particles when the functions of RT and IN are provided *in trans*. This finding demonstrated for the first time for a lentivirus that the full length Gag-Pol precursor is not required for the formation of infectious particles. Our data also show that trans Vpr-RT-IN, or Vpr-RT together with Vpr-IN are fully functional and support virus infectivity, integration of the proviral DNA, and replication (through one cycle) of RT defective, IN defective and RT-IN defective viruses (Liu, H. et al., *J. Virol.* 1997, 71:7704-7710; Wu, X. et al., *J. Virol.* 1994, 68:6161-6169). It should also be noted that our data demonstrate that enzymatically active RT does not require Vpr for incorporation into virions (Figure 19A and B). RT can be incorporated into HIV-1 virions when expressed *in trans* even without its

expression as a fusion partner of Vpr. These data demonstrate that the functions of these critical enzymes can be provided *in trans*, independent of their normal mechanism for expression and virion incorporation as components of the Gag-Pol precursor protein.

- 5           The prior art is deficient in the lack of effective means of delivering or targeting foreign, e.g., toxic, proteins to virions. The present invention fulfills this longstanding need and desire in the art.

#### SUMMARY OF THE INVENTION

- 10           The present invention shows that Gag and/or Gag variants can be used as vehicles to target proteins of viral and non-viral origin into HIV/SIV virions. Gag gene fusions were constructed with bacterial staphylococcal nuclease (SN), chloramphenicol acetyl transferase (CAT) genes, green fluorescence protein (GFP), reverse transcriptase (RT), integrase (IN) and combinations thereof. Fusion proteins containing a Gag  
15 moiety should be packaged into HIV particles by expression *in trans*, to the native viral genome.

- Gag fusion proteins were constructed and their abilities to package into HIV particles were demonstrated. The present invention shows that Gag fusion proteins were expressed in mammalian cells and were incorporated into HIV particles even in  
20 the presence of wild-type Gag proteins. The present invention further shows that virion incorporated *Gag fusions remain infective in contrast to the prior art (G. Schuman et al., J. Virol. 1996, 70:4379-37)*. Thus, targeting heterologous Gag fusion proteins, including deleterious enzymes, to virions represents a new avenue toward anti-HIV drug discovery and gene therapy.

- 25           The invention shows that Gag proteins and variants thereof are operative as vehicles to deliver fully functional RT and IN *in trans* into lentiviral and retroviral particles, independently of their normal expression as components of the Gag-Pol precursor protein. Therefore, this invention generates a novel packaging component (Gag-Pro), and a novel transenzymatic element that provides enzyme function for  
30 retroviral-based vectors. According to the present invention, the generation of potentially infectious/ replicating retroviral forms (LTR-gag-pol-LTR) is decreased, since according to the present invention this requires recombination of at least three separate RNAs derived from the different plasmids: vector plasmid, packaging plasmid,

a trans-enzyme expression plasmid and envelope plasmid, and as such is unlikely to occur. Virion Gag proteins are utilized in the present invention as vehicles to deliver the RT and IN proteins into lentiviral vectors, independently of Gag-Pol. As Such, a "trans-lentiviral" or "transretroviral" vector is utilized for gene delivery, and gene therapy.

In one embodiment of the present invention, there is provided a composition of matter, comprising: DNA encoding a viral Gag protein fused to DNA encoding a virus inhibitory protein.

In another embodiment of the present invention, there is provided a composition of matter, comprising: DNA encoding a viral Gag protein truncate fused to DNA encoding a virus inhibitory protein.

In yet another embodiment of the present invention, there is provided a method of delivering a virus inhibitory molecule to a target in an animal, comprising the step of administering to said animal an effective amount of the composition of the present invention.

In still yet another embodiment of the present invention, there is provided a pharmaceutical composition, comprising a composition of the present invention and a pharmaceutically acceptable carrier.

Other and further aspects, features, and advantages of the present invention will be apparent from the following description of the presently preferred embodiments of the invention given for the purpose of disclosure.

#### BRIEF DESCRIPTION OF THE DRAWINGS

So that the matter in which the above-recited features, advantages and objects of the invention, as well as others which will become clear, are attained and can be understood in detail, more particular descriptions of the invention briefly summarized above may be had by reference to certain embodiments thereof which are illustrated in the appended drawings. These drawings form a part of the specification. It is to be noted, however, that the appended drawings illustrate preferred embodiments of the invention and therefore are not to be considered limiting in their scope.

Figures 1A-D shows the construction of *vpr1*, *vpr1SN/SN\**, *vpx2* and *vpx2SN/SN\** expression plasmids. Figure 1A shows the illustration of the pTM-*Vpr1* expression plasmid. The HIV-1<sub>YU2</sub> *vpr* coding region was amplified by PCR and

ligated into pTM 1 at the NcoI and BamHI restriction sites. Figure 1B shows the illustration of the pTM-vpx2 expression plasmid. The HIV-2<sub>ST</sub> *vpx* coding region was amplified by PCR and ligated into pTM1 at the NcoI and BglII/SmaI sites. Figure 1C shows the illustration of the fusion junctions of the pTM-vpr1SN/SN\* expression plasmids. SmaI/XhoI DNA fragments containing SN and SN\* were ligated into HpaI/XhoI cut pTM-vpr1. Blunt-end ligation at HpaI and SmaI sites changes the *vpr* translational stop codon (TAA) to Trp and substituted the C terminal Ser with a Cys residue. Figure 1D shows the illustration of the fusion junctions of the pTM-vpx2SN/SN\* expression plasmids. BamHI/XhoI DNA fragments containing SN and SN\* were ligated into BamHI/XhoI cut pTM-vpx2. In the construction of these plasmids, the Vpx C terminal Arg codon was changed to a Val codon and a Ser residue was introduced in place of the Vpx translational stop codon (TAA). Fusion of *vpx* and SN/SN\* at the BamHI sites left a short amino acid sequence of the pTM1 polylinker (double underlined) between the two coding regions.

Figures 2A and B shows the expression of Vpr1- and VPX2- SN and SN\* fusion proteins in mammalian cells. Figure 2A shows the pTM1, pTM-vpr1, pTMvpr1SN and pTM-vpr1SN\* were transfected into HeLa cells one hour after infection with rVT7 (MOI = 10). Twenty-four hours later cell lysates were prepared and examined by immunoblot analysis. Replica blots were probed with anti-Vpr1 (left) and anti-SN (right) antibodies. Figure 2B shows that replica blots, prepared from rVT7 infected HeLa cells transfected with pTM1, pTM-vpx2, pTM-vpx2SN and pTM-vpx2SN\*, were probed with anti-Vpx2 (left) and anti-SN (right) antibodies. Bound antibodies were detected by ECL (Amersham) methods as described by the manufacturer.

Figures 3A and B shows the incorporation of Vpr1- and Vpx2- SN and SN\* fusion proteins into virus-like particles (VLP). Figure 3A transfection of T7 expressing (rVT7 infected) HeLa cells with pTM-vpr1, pTM-vpr1SN, and pTM-vpr1SN\* alone and in combination with pTM-gagl. pTM1 was also transfected for control. Culture supernatants were collected twenty-four hours after transfection, clarified by centrifugation (1000 X g, 10 min.) and ultracentrifuged (125,000 X g, 2 hrs.) over cushions of 20% sucrose. Pellets (VLPs, middle and bottom panels) and cells (top panel) were solubilized in loading buffer and examined by immunoblot analysis using anti-Vpr1 (top and middle) and anti-Gag (bottom) antibodies as probes. Figure 3B

transfection of T7 expressing HeLa cells pTM-vpx2, pTM-vpx2SN and pTM-vpx2SN\* alone and in combination with pTM-gag2. Pellets (VLPs, middle and bottom panels) and cells (top panel) were lysed, proteins were separated by SDS-PAGE and electroblotted to nitrocellulose as described above. Replica blots were probed with anti-Vpx2 (top and middle panels) and anti-Gag (bottom panel) antibodies. Bound antibodies were detected using ECL methods.

Figures 4A and B shows that virus-specific signals mediate incorporation of Vpr- and Vpx- SN into VLPs. Figure 4A shows that HIV- 1 Gag mediates packaging of Vpr1SN. rVT7 infected (T7 expressing) HeLa cells were transfected with pTM-vpr1SN alone and in combination with pTM-gag2 and pTM-gag1. Pellets (VLPs, middle and bottom panels) and cells (top panel) were prepared 24 hours after transfection and examined by immunoblot analysis using anti-Vpr 1 (top and middle) and anti-Gag (bottom) antibodies for probes. (B) HIV-2 Gag mediates packaging of Vpx2SN. T7 expressing HeLa cells were transfected with pTM-vpx2SN alone and in combination with pTM-gag1 and pTM-gag2. Pellets (VLPs, middle and bottom panels) and cells (top panel) were prepared 24 hours after transfection and examined by immunoblot analysis using anti-Vpx2 (top and middle) and anti-Gag (bottom) antibodies for probes.

Figures 5A and B shows a competition analysis of Vpr1SN and Vpx2SN for incorporation into VLPs. Figure 5A shows transfection of T7 expressing HeLa cells with different amounts of pTM-vpr1 (2.5, 5 and 10 ug) and pTM-vpr1SN (2.5, 5 and 10 ug), either individually or together in combination with pTMgag1 (10 ug). Figure 5B shows that HeLa cells were transfected with different amounts of pTM-vpx2 (2.5, 5 and 10 ug) and pTM-vpx2SN (2.5, 5 and 10 ug), either individually or together with pTM-gag2 (10 ug). Twenty hours after transfection, particles were concentrated by ultracentrifugation through sucrose cushions and analyzed by immunoblotting using anti-Vpr1 (A) or anti-Vpx2 (B) antibodies.

Figures 6A - C shows the nuclease activity of VLP-associated Vpr1SN and Vpx2SN proteins. Virus-like particles were concentrated from culture supernatants of T7 expressing HeLa cells cotransfected with pTM-gag1/pTMvpr1SN, pTM-gag1/pTM-vpr1SN\*, pTM-gag2/pTM-vpx2SN and pTMgag2/pTM-vpx2SN\* by ultracentrifugation (125,000 X g, 2 hrs.) through 20% cushions of sucrose. Pellets containing Vpr1- SN and SN (B) and Vpx2- SN and SN\* (C) were resuspended in

PBS. Tenfold dilutions were made in nuclease reaction cocktail buffer (100 mM Tris-HCl pH 8.8, 10 mM CaCl<sub>2</sub>, 0.1% NP40) and boiled for 1 minute. Five ul of each dilution was added to 14 ul of reaction cocktail buffer containing 500 ng of lambda phage DNA (HindIII fragments) and incubated at 37°C for 2 hours. Reaction products were electrophoresed on 0.8% agarose gels and DNA was visualized by ethidium bromide staining. Standards (A) were prepared by dilution of purified staphylococcal nuclease (provided by A. Mildvan) into cocktail buffer and assayed.

Figures 7 A – D shows the incorporation of Vpx2SN into HIV-2 by *trans* complementation. Figure 7A shows the construction of the pLR2Pvpx2SN/SN\* expression plasmids. To facilitate efficient expression of HIV genes, the HIV-2 LTR and RRE were engineered into the polylinker of pTZ19U, generating pLR2P. The organization of these elements within the pTZ19U polylinker is illustrated. NcoI/XhoI *vpx2SN* and *vpx2SN\** (*vpxSN/SN\**) containing DNA fragments were ligated into pLR2P, generating pLR2P-*vpx2SN* and pLR2P-*vpx2SN\** (pLR2P-*vpxSN/SN\**).

Figure 7B shows the association of Vpx2SN with HIV-2 virions. Monolayer cultures of HLtat cells were transfected with HIV-2<sub>ST</sub> proviral DNA (pSXB1) and cotransfected with pSXB1/pTM-*vpx2SN* and pSXB1/pTM-*vpx2SN\**. Extracellular virus was concentrated from culture supernatants forty-eight hours after transfection by ultracentrifugation (125,000 X g, 2 hrs.) through cushions of 20% sucrose. Duplicate Western blots of viral pellets were prepared and probed independently with anti-Vpx2 (left) anti-SN (middle) and anti-Gag (right) antibodies. Figure 7C shows a sucrose gradient analysis. Pellets of supernatant-virus prepared from pSXB1/pTM-*vpx2SN* cotransfected HLtat cells were resuspended in PBS, layered over a 20-60% linear gradient of sucrose and centrifuged for 18 hours at 125,000 X g. Fractions (0.5 ml) were collected from the bottom of the tube, diluted 1:3 in PBS, reprecipitated and solubilized in electrophoresis buffer for immunoblot analysis. Replica blots were probed with anti-SN (top) and anti-Gag (bottom) antibodies. Fraction 1 represents the first collection from the bottom of the gradient and fraction 19 represents the last collection. Only alternate fractions are shown, except at the peak of protein detection.

Figure 7D shows the incorporation of Vpx2SN into HIV-2<sub>7312A</sub> Vpr and Vpx competent virus. Virus concentrated from supernatants of HLtat cells transfected with HIV-2<sub>7312A</sub> proviral DNA (pJK) or cotransfected with pJK/pLR2P-*vpx2SN* or

pJK/pLR2P-vpx2SN\* was prepared for immunoblot analysis as described above. Included for control were virions derived by pSXB1/pLR2P-vpx2SN\* cotransfection. Duplicate blots were probed with anti-Vpx (left) and anti-Gag (right) antibodies.

Figures 8 A - C shows the incorporation of Vpr1SN into HIV-1 virions by *trans* complementation. Culture supernatant virus from HLTat cells transfected with pNL4-3 (HIV-1) and pNL4-3R- (HIV-1 vpr mutant) or cotransfected with pNL4-3/pLR2P-vpr1SN and pNL4-3R-/pLR2P-vpr1SN was prepared for immunoblot analysis as described above. Blots were probed with anti-SN (Figure 8A), anti-Vpr1 (Figure 8B) and anti-Gag (Figure 8C) antibodies.

Figure 9 shows the inhibition of Vpr1/Vpx2-SN processing by an HIV protease inhibitor. HIV-1 (pSG3) and HIV-2 (pSXB1) proviral DNAs were cotransfected separately into replica cultures of HLTat cells with pLR2Pvpr1SN and pLR2P-vpx2SN, respectively. One culture of each transfection contained medium supplemented with 1  $\mu$ M of the HIV protease inhibitor L699-502. Virions were concentrated from culture supernatants by ultracentrifugation through cushions of 20% sucrose and examined by immunoblot analysis using anti-Gag (Figure 9A) and anti-SN (Figure 9B) antibodies.

Figures 10 A - D shows the incorporation of enzymatically active Vpr1- and Vpx2- CAT fusion proteins into HIV virions. Figure 10A shows an illustration of the fusion junctions of the pLR2P-vpr1CAT and pLR2P-vpx2CAT expression plasmids. PCR amplified BamHI/XhoI DNA fragments containing *CAT* were ligated into BglII/XhoI cut pLR2P-vpr1 SN and pLR2P-vpx2SAN, replacing SN (see Figure 1). This construction introduced two additional amino acid residues (Asp and Leu, above blackened bar) between the *vpr1/vpx2CAT* coding regions. Figure 10B shows the incorporation of Vpr1CAT into HIV-1 virions. Virus produced from HLTat cells transfected with pNL4-3 (HIV-1) and pNL4-3R- (HIV-1-R-), or cotransfected with pNL43/pLR2P-vpr1CAT and pNL4-3R-/pLR2P-vpr1CAT was prepared as described above and examined by immunoblot analysis. Replica blots were probed with anti-Vpr1 (left) and anti-Gag (right) antibodies. Figure 10C shows the incorporation of Vpx2CAT into HIV-2 virions. Virus produced from HLTat cells transfected with pSXB1 (HIV-2) or cotransfected with pSXB1/pLR2Pvpx2CAT was prepared as described above and examined by immunoblot analysis. Replica blots were probed with anti-Vpx2 (left) and anti-Gag (right) antibodies. Figure 10D shows that virion incorporated Vpr1- and Vpx2- CAT fusion proteins possess enzymatic activity.

Viruses pelleted from HLtat cells transfected with pSXB1 (HIV-2) or cotransfected with pSXB1/pLR2Pvpx2CAT and pNL4-3/pLR2P-vpr1CAT were lysed and analyzed for CAT activity. HIV-2 was included as a negative control.

Figures 11 A - D shows virion association of enzymatically active CAT and SN fusion proteins. Figure 11A shows that HIV-2 virions collected from the culture supernatant of HLtat cells cotransfected with pSXB1 and pLR2P-vpx2 were sedimented in linear gradients of 20-60% sucrose. 0.7 ml fractions were collected and analyzed by immunoblot analysis using Gag monoclonal antibodies as a probe. Figure 11B shows CAT enzyme activity was determined in each fraction by standard methods. The positions of nonacetylated [<sup>14</sup>C] chloramphenicol (Cm) and acetylated chloramphenicol (Ac-Cm) are indicated. Figure 11C shows HIV-1 virions derived from HLtat cells cotransfected with pSG3 and pLR2P-vpr1SN and cultured in the presence of L689,502 were sedimented in linear gradients of 20-60% sucrose. Fractions were collected and analyzed for virus content by immunoblot analysis using Gag monoclonal antibodies. Figure 11D shows that SN activity was determined in each fraction as described in Figure 6.

Figures 12 A - C shows the HIV-1 genome, the construction of pΔ8.2, pCMV-VSV-G, pHR-CMV-β-gal, pCR-gag-pro, pLR2P-vpr-RT-IN, pCMV-VSV-G and pHR-CMV-β-gal plasmids. Figure 12A shows an illustration of the HIV-1 genome. Figure 12B shows the lentivirus vector plasmid expression system. Figure 12C shows the illustration of a trans-lentiviral vector expression system, where RT and IN are contiguous as Vpr fusion partners.

Figure 13 shows positive gene transduction with a trans-lentiviral vector of the instant invention as determined by fluorescence microscopy.

Figure 14 shows positive gene transduction with a lentiviral vector as a control as determined by fluorescence microscopy.

Figure 15 shows the construction of a pHR-CFTR trans-lentiviral vector of the present invention.

Figure 16 shows the expression of CFTR on HeLa cells using the trans-lentiviral vector, and the lentiviral vector as a control. Transduced cells were probed with polyclonal antibodies in immunofluorescence microscopy.

Figure 17 shows the expression of CFTR on HeLa cells using monoclonal antibodies in immunofluorescence microscopy.

Figure 18 shows the restoration of CFTR function *in trans*-lentiviral transduced HeLa cells as measured by a halide sensitive fluorophore.

Figures 19A and B show the presence in progeny virions of RT *in trans* without Vpr-dependent incorporation.

5        Figure 20 shows that both Vpr-RT and RT support vector transduction when provided *in trans*.

Figure 21 shows component constructs of a trans-retroviral vector according to the present invention. Figure 21A shows a pCMV, Gag-Pro packaging plasmid. Figure 21B shows a pCMV, GagNC-RT-IN trans-enzyme expression plasmid. Figure 21C  
10        shows a vector plasmid. Figure 21D shows an envelope plasmid construct operative in the present invention.

Figure 22 shows component constructs of a retroviral vector according to the present invention. Figure 22A shows a pCMV, Gag-Pro-RT-IN retroviral packaging plasmid. Figures 22B and C are the vector plasmid and envelope plasmids of Figures  
15        21C and D, respectively.

Figure 23 shows component constructs of a lentiviral vector according to the present invention. Figure 23A shows a pTRE, Gag-Pro-RT-IN packaging plasmid. Figure 23B shows a pHR-CTS, CMV, GFP, WPRE lentiviral vector plasmid. Figure 23C is the envelope plasmid at Figure 21D.

20        Figures 24A-C show representative trans-lentiviral trans-enzyme plasmids according to the present invention indicating Pro cleavage sites and zinc finger locations.

#### DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

25        As used herein, the term "fusion protein" refers to either the entire native protein amino acid sequence of Vpx (of any HIV-2 and SIV) or Vpr (of any HIV-1 and SIV) or retroviral Gag or any subtraction of their sequences that have been joined through recombinant DNA technology and are capable of association with either native HIV/SIV virions or a retrovirus-like particle.

30        As used herein, the term "virion" refers to HIV-1, HIV-2 and SIV virus particles.

As used herein, the term "retrovirus-like particle" refers to any composition of HIV-1, HIV-2, SIV or retrovirus proteins other than which exists naturally in naturally

infected hosts that are capable of assembly and release from either natural or immortalized cells that express these proteins.

As used herein, the term "variant" refers to a polypeptide or nucleotide sequence having at least 30% sequence identity with the native sequence including fragments thereof as calculated by Fast DB as per "Current Methods in Sequence Comparison and Analysis," Macromolecule Sequencing and Synthesis, Selected Methods and Applications, pp. 127-149.

As used herein, the term "transfect" refers to the introduction of nucleic acids (either DNA or RNA) into eukaryotic or prokaryotic cells or organisms.

As used herein, the term "gene transduction element" refers to the minimal required genetic information to transduce a cell with a gene.

As used herein, the term "virus-inhibitory protein" refers to any sequence of amino acids that have been fused with Vpx or Vpr or Gag sequences that may alter in any way the ability of a retrovirus to multiply and spread in either individual cells (prokaryotic and eukaryotic) or in higher organisms. Such inhibitory molecules may include: HIV/SIV proteins or sequences, including those that may possess enzymatic activity (examples may include the HIV/SIV protease, integrase, reverse transcriptase, Vif and Nef proteins) HIV/SIV proteins or proteins/peptide sequences that have been modified by genetic engineering technologies in order to alter in any way their normal function or enzymatic activity and/or specificity (examples may include mutations of the HIV/SIV protease, integrase, reverse transcriptase, Vif and Nef proteins), or any other non-viral protein that, when expressed as a fusion protein with Vpr or Vpx or Gag, alter virus multiplication and spread in vitro or in vivo.

In the present invention, the HIV Vpr and Vpx proteins were packaged into virions through virus type-specific interactions with the Gag polyprotein precursor. HIV-1 Vpr (Vpr1) and HIV-2 Vpx (Vpx2) are utilized to target foreign proteins to the HIV particle as their open reading frames were fused inframe with genes encoding the bacterial staphylococcal nuclease (SN), an enzymatically inactive mutant of SN (SN\*), and the chloramphenicol acetyl transferase (CAT). Transient expression in a T7-based vaccinia virus system demonstrated the synthesis of appropriately sized Vpr1SN/SN\* and Vpx2SN/SN\* fusion proteins which, when co-expressed with their cognate p55<sup>Gag</sup> protein, were efficiently incorporated into virus-like particles (VLPs). Packaging of the fusion proteins was dependent on virus type-specific determinants, as previously seen

with wild-type Vpr and Vpx proteins. Particle associated Vpr1SN and Vpx2SN fusion proteins were enzymatically active as determined by *in vitro* digestion of lambda phage DNA. To demonstrate that functional Vpr1 and Vpx2 fusion proteins were targeted to HIV particles, the gene-fusions were cloned into an HIV-2 LTR/RRE regulated expression vector and co-transfected with wild-type HIV-1 and HIV-2 proviruses. Western blot analysis of sucrose gradient purified virions revealed that both Vpr1 and Vpx2 fusion proteins were efficiently packaged regardless of whether SN, SN\* or CAT were used as C terminal fusion partners. Moreover, the fusion proteins remained enzymatically active and were packaged in the presence of wild-type Vpr and Vpx proteins. Interestingly, virions also contained smaller sized proteins that reacted with antibodies specific for the accessory proteins as well as SN and CAT fusion partners. Since similar proteins were absent from Gag-derived VLPs as well as in virions propagated in the presence of an HIV protease inhibitor, they must represent cleavage products produced by the viral protease. Taken together, these results demonstrate that Vpr and Vpx can be used to target functional proteins, including potentially deleterious enzymes, to the HIV/SIV particle. These properties are useful for the development of novel antiviral strategies.

In the present invention, a gene cassette is coupled to a retrovirus Gag variant within a trans-enzyme plasmid to induce fusion protein expression of the gene. Through selection of the gene and modification of the Gag nucleotide sequence, the vectors of the present invention are operative as antiviral therapeutics and/or gene delivery vectors when transfected into host cells in conjunction with genes or variants thereof coding packaging, vector and envelope polypeptides. While the present invention is detailed herein with plasmids each encoding different vector functions, it is appreciated that such functions are readily combined into a lesser number of plasmids including one, two and three plasmids which are cotransfected into a host cell. Preferably, a multiple plasmid gene delivery system is utilized according to the present invention.

A Gag based trans-lentiviral vector was produced by transfecting 293T cells with the pCMV-gag-pro (packaging plasmid), a different trans-enzyme plasmid based on Gag, the pPCMV-eGFP (transfer vector), and the pMD-G (env plasmid). The Gag based trans-lentiviral vector of the present invention demonstrates that the Gag precursor protein is able to deliver functional fusion proteins to a host cell. The fusion

proteins illustratively include RT, IN, RT-IN, GFP, CAT, CFTR and the like. As a control, trans-lentiviral vector based Vpr was produced by transfecting 293T cells with the pCMV-gag-pro (packaging plasmid), the pLR2P-Vpr-RTIN (trans-enzyme plasmid), the pPCMV-eGFP (transfer vector), and the pMD-G (env plasmid) (Wu, X. et al., *EMBO Journal* 1997, 16:5113-5122 (1997)). Using fluorescence microscopy to monitor GFP expression, the infectivity of the trans-lentiviral vector particles was monitored on monolayer cultures of HeLa cells. As shown in Table 1, the titer of the trans-lentiviral vector based on Gag ranged from  $0.4$  to  $4 \times 10^5$  /ml, while that of the trans-lentiviral vector based on Vpr ranged from  $5$  to  $9 \times 10^5$  /ml. The Gag precursor protein according to the present invention is capable of delivering functional proteins into the vector particles. Reproducibly, the titer of the trans-lentiviral vector based Gag was approximately 2-5 fold less than that of the trans-lentiviral vector based Vpr for RT-IN.

15

Table 1

Titers of Trans-Lentiviral GagRTIN Vectors

	Constructs	Trans-Lentiviral Delivery Vectors	Control	
			Viral Titer	Viral Titer*
	A	PTRE, GagNC-RT-IN,RRE- 1	$3.5 \times 10^4$	$5 \times 10^5$
20	B	pPLR2P-GagNC(IZF)-RT-IN,RRE-2**	$3.75 \times 10^5$	$6.5 \times 10^5$
	C	pLR2P-CA-RT-IN,RRE-2***	$1.25 \times 10^5$	$8.75 \times 10^5$
	D	pLR2P-GagNC-RT-IN,RRE-2	$2.5 \times 10^5$	$5 \times 10^5$
	E	pLR2P-GagNC( $\Delta$ PC)-RT-IN,RRE-2****	$1.25 \times 10^5$	$5 \times 10^5$

- \* pLR2P-Vpr-RT-IN plasmid was used as positive control.  
 25 \*\* The 3' Zinc Finger domain was deleted in the NC domain of this construct.  
 \*\*\* The whole NC domain was deleted in this construct.  
 \*\*\*\* Only the Pro-RT protease cleavage site exists between the Gag and RT domains of this construct.

30

The ability of trans-RT-IN to support virus infectivity of the lentivirus parties (virions derived from RT-IN minus proviral DNA of HIV-1) or a lentivirus-based vector, indicates that trans-RT-IN fusion protein is readily substituted for cis-acting RT-IN. To determine whether the trans-RT-IN (derived from the Gag-RT-IN fusion protein) of a simple retrovirus, like the lentivirus, also Cis acting RT-IN derived from

35

the native Gag-Pol structure (GAG-PR-RT-IN) is replaced by trans-RT-IN derived from Gag-RT and Gag-IN or a triple fusion of Gag-RT-IN in a retrovirus such as a lentivirus. Thus, a trans-retroviral vector based Gag was produced by transfecting 293T cells with the 5 ug of packaging construct (pCMV-ATG/gag-pro), 2 ug of the transenzyme plasmid (pCMV-ATG/gag-RT-IN), 5 ug of the transfer vector (pRTCMV-eGFP-WPRE) and the pMD-G (env plasmid). As a control, the retrovirus vector was produced by transfecting 293T cells with the pCMVATG/gag-pol (packaging plasmid), 5 ug of the transfer vector (pRTCMV-eGFP-WPRE) and the pMD-G (env plasmid). Using fluorescence microscopy to monitor GFP expression, the infectivity of the trans-lentiviral vector particles was monitored on monolayer cultures of HeLa cells. As shown in Table 2, the titer of the trans-retrovirus vector ranged from 0.6 to 1.8 X 10<sup>7</sup>/ml. Retrovirus vector titers ranged from 0.8 to 2.5 x 10<sup>7</sup>/ml. This result demonstrates that the simple rgag precursor protein of a retrovirus also can deliver the functional proteins into a vector particle *in trans*. Thus, according to the present invention gene delivery to a host cell occurs with a Gag precursor gene a fusion partner to a protein of interest, thereby making a variety of retroviruses operative as gene delivery vector systems.

Table 2

Titers of the Trans-Retroviral and Retroviral Vectors				
Trans-enzyme Plasmid	Packaging Plasmid	Vector Plasmid	Envelope Plasmid	Viral Titer
NA*	pCMV,Gag-Pro-RT-IN	pRT-CMV,GFP,WPRE	PMD-G	7.18X 10 <sup>6</sup>
NT**	pCMV,Gag-Pro	pRT-CMV,GFP,WPRE	PMD-G	6X 10 <sup>3</sup>
pCMV,GagNC-RT-IN	NT**	pRT-CMV,GFP,WPRE	PMD-G	0
pCMV,GagNC-RT-IN	pCMV,Gag-Pro	pRT-CMV,GFP,WPRE	PMD-G	1.78X 10 <sup>7</sup>
<hr/>				
* NA	not applicable			
** NT	Not transfected			

### Methods

(1) Vector particles were generated by DNA transfection into 293T cells.

(2) Vector titers were determined by infecting HeLa cells. The results are expressed as infectious particles/ml of culture supernatant collected from transfected 293T cells.

5           Gag fusions are operative here from retroviruses and lentiviruses including Moloney Leukemia Virus (MLV), Abelson murine leukemia virus, AKR (endogenous) murine leukemia virus, Avian carcinoma, Mill Hill virus 2, Avian leukosis virus - RSA, Avian myeloblastosis virus, Avian myelocytomatosis virus 29, Bovine syncytial virus, Caprine arthritis encephalitis virus, Chick syncytial virus, Equine infectious anemia  
10 virus, Feline leukemia virus, Feline syncytial virus, Finkel-Biskis-Jenkins murine sarcoma virus, Friend murine leukemia virus, Fujinami sarcoma virus, Gardner-Arnstein feline sarcoma virus, Gibbon ape leukemia virus, Guinea pig type C oncovirus, Hardy-Zuckerman feline sarcoma virus, Harvey murine sarcoma virus, Human foamy virus, Human spumavirus, Human T-lymphotropic virus  
15 1, Human T-lymphotropic virus 2, Jaagsiekte virus, Kirsten murine sarcoma virus, Langur virus, Mason-Pfizer monkey virus, Moloney murine sarcoma virus, Mouse mammary tumor virus, Ovine pulmonary adenocarcinoma virus, Porcine type C oncovirus, Reticuloendotheliosis virus, Rous sarcoma virus, Simian foamy virus, Simian sarcoma virus, Simian T-lymphotropic virus, Simian type D virus 1, Snyder-  
20 Theilen feline sarcoma virus, Squirrel monkey retrovirus, Trager duck spleen necrosis virus, UR2 sarcoma virus, Viper retrovirus, Visna/maedi virus, Woolly monkey sarcoma virus, and Y73 sarcoma virus human-, simian-, feline-, and bovine immunodeficiency viruses (HIV, SIV, FIV, BIV). While RT and TN fusions with Gag are operative herein, it is appreciated that a variety of therapeutic and diagnostic fusion  
25 proteins are similarly deliverable to a target cell according to the methodologies and vectors disclosed herein.

          Gag-based trans-lentiviral vectors are disclosed based on non-primate lentiviruses and simple retroviruses encoding retrovirus Gag precursor proteins which have functions akin to those of primate lentiviral Vpr or Vpx proteins. Contrary to the  
30 prior art, the present invention maintains viral infectivity in non-dividing primary cells. The WPRE sequence encoded within a vector of the present invention is necessary therefor. Infectivity of the vectors of the present invention is further enhanced through the use of a gene transfer vector containing the posttranscriptional regulatory element of woodchuck hepatitis virus (WPRE). While the inclusion of a WPRE gene or gene

fragment capable of regulating posttranscription increases trans-lentiviral titer alone, the inclusion of additional PPT-CTS sequences creates a cumulative enhancement in viral infectivity. WPRE has been shown to increase luciferase or GFP production in similar virus-based vectors (R. Zufferey, *J. Virol.* 73, 2886-2892 (1999)).

- 5 Alternatively, the central terminator sequence (CTS) and central polypurine tract (PPT) are introduced into the gene transfer vector and new viral and trans-viral vectors to independently increase titer, as detailed in U.S. Provisional Application 60/164,626 filed November 10, 1999. PPT and CTS have been implicated in HIV-1 reverse transcription. P. Chameau et al., *J. Mol. Biol.* 241, 651-662 (1994). It is also
- 10 appreciated that the other control sequences capable of stabilizing messenger RNA and thereby facilitating protein expression are operative in place of WPRE, PPT and CTS within the present invention.

- The WPRE sequence functions differently than the PPT-CTS. Whereas the latter is thought to promote reverse transcription and nuclear import, the former is
- 15 thought to stabilize transcripts and therefore result in increased translation and product signal. A cumulative effect of these two sequences, when operatively positioned within the same gene transfer vector, has been observed regardless of whether used in a lentiviral or translentiviral system. Functional variations of these two sequences, or functional analogs of these sequences, are also anticipated to exist or to be producible
- 20 without undue experimentation, and to have merit with the invention. By including these sequences (cts-ppt and WPRE) in the lenti- and trans-lentiviral vector systems, the titer, transduction efficiency, and thus utility for transducing cells is enhanced, especially for non-dividing cells, such as muscle, neurons, stem cells, unstimulated CD34+ cells, airway cells, liver cells, cells of the eye, and other somatic cells. Non-
- 25 dividing cells may be defined as somatic cells, cells with a limited life span, or primary cells that divide slowly. However, such cells may also be stimulated to divide more rapidly, e.g., in the instance of CD34+ bone marrow cells, i.e., pluripotent hematopoietic stem cells.

- The present invention provides for a delivery of a trans protein or gene to a viral
- 30 vector through coupling to either a viral protein, or gene delivery, respectively; wherein the viral protein is Vpr or Vpx or Gag and the gene encodes either Vpr or Vpx or Gag. Certain truncation variants of these trans protein or genes perform the regulatory or enzymatic functions of the full sequence protein or gene. For example, the nucleic acid

sequences coding for protease, integrase, reverse transcriptase, Vif, Nef, Gag, RT, IN and CFTR can be altered by substitutions, additions, deletions or multimeric expression that provide for functionally equivalent proteins or genes. Due to the degeneracy of nucleic acid coding sequences, other sequences which encode substantially the same amino acid sequences as those of the naturally occurring proteins may be used in the practice of the present invention. These include, but are not limited to, nucleic acid sequences comprising all or portions of the nucleic acid sequences encoding the above proteins, which are altered by the substitution of different codons that encode a functionally equivalent amino acid residue within the sequence, thus producing a silent change. For example, one or more amino acid residues within a sequence can be substituted by another amino acid of a similar polarity which acts as a functional equivalent, resulting in a silent alteration. Substitutes for an amino acid within the sequence may be selected from other members of the class to which the amino acid belongs. For example, the nonpolar (hydrophobic) amino acids include alanine, leucine, isoleucine, valine, proline, phenylalanine, tryptophan and methionine. The polar neutral amino acids include glycine, serine, threonine, cysteine, tyrosine, asparagine, and glutamine. The positively charged (basic) amino acids include arginine, lysine and histidine. The negatively charged (acidic) amino acids include aspartic acid and glutamic acid. Also included within the scope of the present invention are proteins or fragments or derivatives thereof which are differentially modified during or after translation, e.g., by glycosylation, proteolytic cleavage, linkage to an antibody molecule or other cellular ligands, etc. In addition, the recombinant ligand encoding nucleic acid sequences of the present invention may be engineered so as to modify processing or expression of a ligand. For example, a signal sequence may be inserted upstream of a ligand encoding sequence to permit secretion of the ligand and thereby facilitate apoptosis.

Additionally, a ligand encoding nucleic acid sequence can be mutated *in vitro* or *in vivo* to create and/or destroy translation, initiation, and/or termination sequences or to create variations in coding regions and/or form new restriction endonuclease sites or destroy pre-existing ones, to facilitate further *in vitro* modification. Any technique for mutagenesis known in the art can be used, including but not limited to *in vitro* site directed mutagenesis, (*J. Biol. Chem.* 253:6551), use of Tab linkers (Pharmacia), etc.

The following examples are given for the purpose of illustrating various embodiments of the invention and are not meant to limit the present invention in any fashion.

5    Example I - Cells and Viruses.

HeLa, HeLa-tat (HLtat), 293T and CV-1 cells were maintained in Dulbecco's Modified Eagle's Medium supplemented with 10% fetal bovine serum (FBS), 100 U penicillin and 0.1 mg/ml streptomycin. HLtat cells constitutively express the first exon of HIV-1 *tat* and were provided by Drs. B. Felber and G. Pavlakis. A recombinant  
10    vaccinia virus (rVT7) containing the bacteriophage T7 RNA polymerase gene was used to facilitate expression of viral genes placed under the control of a T7 promoter. Stocks of rVT7 were prepared and titrated in CV-1 cells as described previously by Wu, et al., *J. Virol.* 1992, 66:7104-7112. HIV-1<sub>YU2</sub>, HIV-1 pNL 4-3-R- and pNL 4-3, HIV-1<sub>I11XB2D</sub>, HIV-2<sub>ST</sub>, and HIV-2<sub>7312A</sub> proviral clones were used for the construction of  
15    recombinant expression plasmids and the generation of transfection derived viruses.

Example 2 - Antibodies.

To generate HIV-1 Vpr specific antibodies, the HIV-1<sub>YU2</sub> *vpr* open reading frame was amplified by polymerase chain reaction (PCR) using primers (sense:  
20    5'GCCACCTTTGTCGACTGTAAAAAACT-3' (Seq. Id. No. 1) and antisense: 5'-GTCCTAGGCAAGCTTCCTGGATGC-3') (Seq. Id. No. 2) containing SalI and HindIII sites and ligated into the prokaryotic expression vector, pGEX, generating pGEX-vpr1. This construct allowed expression of Vpr1 as a C terminal fusion protein and glutathione S-transferase (gst), thus allowing protein purification using affinity  
25    chromatography. *E. coli* (DH5a) were transformed with pGEX-vpr1 and protein expression was induced with isopropyl β-D thiogalactopyranoside (IPTG). Expression of the gst-Vpr1 fusion protein was confirmed by SDS-PAGE. Soluble gst-Vpr1 protein was purified and Vpr1 was released by thrombin cleavage using previously described procedures of Smith, et al. (*Gene* 1988, 67:31-40). New Zealand White rabbits were  
30    immunized with 0.4 mg of purified Vpr1 protein emulsified 1:1 in Freund's complete adjuvant, boosted three times at two week intervals with 0.25 mg of Vpr1 mixed 1:1 in Freund's incomplete adjuvant and bled

eight and ten weeks after the first immunization to collect antisera. Additional antibodies used included monoclonal antibodies to HIV-1 Gag (ACT1, and HIV-2 Gag (6D2.6), polyclonal rabbit antibodies raised against the HIV-2 Vpx protein and anti-SN antiserum raised against purified bacterially expressed SN protein.

5

Example 3 - Construction of T7-based expression plasmids.

A DNA fragment encompassing HIV-1 HXB2D<sub>gag</sub> (nucleotides 335-1837) was amplified by PCR using primers (sense: 5'-AAGGAGAG CCATGGGTGCGAGAGCG-3' (Seq. Id. No. 3) and anti-sense: 5'-GGGGATCC CTTTATTG TGACGAGGGG-3' (Seq. Id. No. 4) containing NcoI and BamHI restriction sites (underlined). The PCR product was digested with NcoI and BamHI, purified and ligated into the polylinker of the pTM1 vector, generating pTM-gag1. Similarly, a DNA fragment containing the gag coding region of HIV-2<sub>ST</sub> (nucleotides 547-2113) was amplified by PCR using sense and anti-sense primers 5'-  
15 ATTGTGGGCCATGGGCGCGAGAAAC-3' (Seq. Id. No. 5) and 5'-GGGGGGG CCCCTACTGGTCTTTTCC-3' (Seq. Id. No. 6), respectively. The reaction product was cut with NcoI and SmaI (underlined), purified and ligated into the polylinker of pTM I, generating pTM-gag2.

For expression of Vpr1 under the control of the T7 promoter, a DNA fragment  
20 containing the HIV-1<sub>YU2</sub> *vpr* coding region (nucleotides 5107-5400) was amplified by PCR using primers (sense: 5'-GAAGATCTACCATGG AAGCCCCAGAAGA-3' (Seq. Id. No. 7) and anti-sense: 5'-CGCGGATCCGTTAACATCT ACTGGCTCCATTCTTGCTC-3' (Seq. Id. No. 8) containing NcoI and HpaI/BamHI sites, respectively (underlined). The reaction product was cut with NcoI and BamHI  
25 and ligated into pTM1, generating a pTM-vpr1 (Figure 12A). In order to fuse SN and SN\* in-frame with *vpr1*, their coding regions were excised from pGN1561.1 and pGN1709.3, respectively and through a series of subcloning steps, ligated into the SmaI/XhoI sites of pTM-vpr1, generating pTM-vpr1SN and pTM-vpr1SN\*. This approach changed the translational stop codon of Vpr1 to a Trp codon and the C  
30 terminal Ser residue to a Cys. The resulting junctions between *vpr1* and SN/SN\* are depicted in Figure 12C.

For expression of Vpx2 under T7 control, a DNA fragment containing the HIV-2<sub>ST</sub> vpx coding sequence (nucleotides 5343-5691) was amplified by PCR using primers (sense: 5'GTGCAACACCATGGCAGGCCCCAGA-3' (Seq. Id. No. 9) and anti-sense: 5'-TGCACTGCAGGAAGATCTTAGACCTGGAGGGGGAG GAGG-3' (Seq. Id. No. 10) containing NcoI and BglII sites, respectively (underlined). After cleavage with BglII and Klenow fill-in, the PCR product was cleaved with NcoI, purified and ligated into the NcoI and SmaI sites of pTMI, generating pTM-vpx2 (Figure 12B). To construct in-frame fusions with vpx2, BamHI/XhoI, SN- and SN\*-containing DNA fragments were excised from pTM-vpr1 SN and pTM-vpr1SN\* and ligated into pTM-vpx2, generating pTM-vpx2SN and pTMvpx2SN\*, respectively. This approach introduced one amino acid substitution at the C terminus of Vpx (Val to Arg), changed the translational stop codon of vpx to Ser and left five amino acid residues of the pTMI plasmid polylinker. The resulting junctions between vpx2 and SN/SN\* are depicted in Figure 1D.

#### Example 4 - Construction of HIV LTR-based Vpr or Vpx expression plasmids.

For efficient expression of Vpr and Vpx fusion proteins in the presence of HIV, a eukaryotic expression vector (termed pLR2P) was constructed which contains both an HIV-2 LTR (HIV-2<sub>ST</sub>, coordinates -544 to 466) and an HIV-2 RRE (HIV-2<sub>ROD</sub>, coordinates 7320 to 7972) element (Figure 7A). These HIV-2 LTR and RRE elements were chosen because they respond to both HIV-1 and HIV-2 Tat and Rev proteins. The vpr1, vpr1SN, vpx2 and vpx2SN coding regions were excised from their respective pTM expression plasmids (see Figure 1) with NcoI and XhoI restriction enzymes and ligated into pLR2P, generating pLR2P-vpr1, pLR2P-vpr1SN, pLR2P-vpx2 and pLR2P-vpx2SN, respectively (Figure 7A). For construction and expression of vpr- and vpx-CAT gene fusions, the SN containing regions (BamHI/XhoI fragments) of pLR2P-vpr1SN and pLR2P-vpx2SN were removed and substituted with a PCR amplified BglII/XhoI DNA fragment containing CAT, generating pLR2PVpr1 CAT and pLR2P-vpx2CAT, respectively (Figure 9A).

#### Example 5 - Construction of lentiviral plasmids involving Gag fusions.

The pHRCMV-eGFP plasmid was derived by modifying pHRCMV-LacZ, which has been described (Naldini, L. et al., *Science* 1996, 272:263-267). The pHRCMV-eGFP plasmid was constructed by ligating a BamHI/XhoI DNA fragment containing eGFP (derived from pEGFP-C1; (CLONTECH Laboratories, Palo Alto, CA) into the pHRCMV-Iacz plasmid after removing lacZ by digestion with BamHI and XhoI. To construct the pPCMV-eGFP, a 150 bp sequence (with coordinates 4327-4483) and containing the central PPT and central terminal site (CTS) was amplified from the SG3 molecular clone by PCR and ligated into pHRCMV-eGFP that was cut with ClaI. To construct the Tet-inducible expression plasmids, 430 bps of TRE-inducible promoter derived from pTRE; (CLONTECH Laboratories, Palo Alto, CA), was cut by Xho I filled to blunt ends and Bam HI. The CMV promoter of pcDNA3.1(+) plasmid (Invitrogen, CA) was replaced using SpeI 1 (filled to blunt ends) and BamHI, generating pTRE-neo. The 6.7 kb of the fragments containing the HIV-based packaging components derived from pCMVgag-pol was cloned into pTRE-neo using EcoR I., and Xho I, generating pTRE-gag-pol which contains functional vif, tat, rev, gag and pol genes. To construct the RT-IN minus plasmid shown in Figure 23A, the region (from 1975 to 5337) of pTREgag-pol were substituted with an RT-IN containing BclI/SalI DNA fragment (from 1975 to 5337) of pSG3S-RT was ligated into the BclI and SalI sites of the pTREgag-pol plasmid, generating pTREgag-pro. The RT-IN sequence contained translational stop codons (TAA) at the first amino acid position of the RT and IN coding regions and was under control of CMV promoter. A 39-base pair internal deletion in the 4 sequence was introduced, the internal region (1357 bp) of envelope gene was deleted from 5827 to 7184, generating pCMVgag-pol. To construct the RT-IN minus plasmid, the region (from 1975 to 5337) of pCMVgag-pol were substituted with an RT-IN containing BclI/SalI DNA fragment (from 1975 to 5337) of pSG3S-RT was ligated into the BclI and SalI sites of the pCMVgag-pol plasmid, generating pCMVgag-pro shown in Table 2. The RT-IN sequence contained translational stop codons (TAA) at the first amino acid position of the RT and IN coding regions. To construct the series of trans-enzyme plasmids shown in Figure 24A-C and Table 2, different fragments of HIV-1 gag genes were amplified by PCR and were cloned into pLR2PvprRTIN using NcoI I and Bgl II, generating a series of gag-RTIN fusion expression plasmids. pLR2gagNC-RTIN shown in Table 1 as construct D contained the Gag gene with the p6 portion deleted. pLR2PgagNC(1ZF)-

RTIN shown in Figure 24B and construct contained the Gag gene with the second 1ZF of NC and p1-p6 fragment deleted. pLR2PgagCA-RTIN shown as Figure 24C and in Table 1 as construct C contained the Gag gene which deleted the NC-p1-p6 fragment. pLR2PVprRTIN construction is described in regard to Figure 12. pMD-G is  
 5 constructed according to existing techniques (Wu, X. et al., *EMBO Journal* 1997, 16:5113-5122 (1997)).

Example 6 - Construction of retroviral plasmids involving Gag fusions.

10 A RT-RN minus packaging construct is formed based on Moloney murine leukemia virus pCMV-ATG/gag-pol was cut by Sal I and filled with Klenow, generating pCMV-ATG/gag-pro, with the RT gene being mutated by the reading frame shift at the position of 366 aa as shown in Figure 21A. A trans-enzyme plasmid, the 312 bp of fragment which contains protease region was deleted from the gag-pol of  
 15 pCMV-ATG/gag-pol, generating pCMVATG/gag-RT-IN as shown in Figure 21B. The GFP transfer vector based on Moloney murine leukemia virus, GFP-WPRE which was obtained from pPCMV-eGFP-WPRE (M.H. Finer et al., *Blood* 1994, 83:43-50) and cloned into pRTCMV using BamH I and Apol I, generating pRTCMV-eGFP-WPRE as shown in Figure 21 C.

20

Example 7 - Preparation of vector stocks and infection.

Trans-lentiviral vector stocks were produced by transfecting the 5 ug of packaging construct (pTREgag-pol), the 2 ug of VSV-G construct (PMD-G), and 5 ug  
 25 of the transfer vector (pPCMV-eGFP WPRE) and 1 ug of pTet-off (CLONTECH Laboratories, Palo Alto, CA) and different trans-enzyme plasmids into the subconfluent 293T cell by the calcium phosphate precipitation method. Trans-retroviral vector stocks were produced by transfecting the 5 ug of packaging construct (pCMV-ATG/gag-pro), the 2 ug of VSV-G construct (pMD-G), and 5 ug of the transfer vector  
 30 (pRTCMV-eGFP-WPRE) and 2 ug of the trans-enzyme plasmid (pCMV-ATG/gag-RT-IN). Approximately  $1 \times 10^6$  cells were seeded into six-well plates 24 hr prior to transfection. The vector stocks were harvested 60 hr post transfection. Supernatants of the transfected cultures were clarified by low speed

centrifugation (1000 g, 10 min), and filtered through a 0.45-um-pore size filter, aliquoted and subsequently frozen at -80°C. The target cell were infected in the DMEM-1% FBS containing 10 ug/ml of DEAEtestron for 4 hr at 37°C. The medium was subsequently replaced with fresh DMEM-10% FBS or preconditional medium. To  
5 determine the titer of eGFP vector, the supernatant stock of 1.0, 0.2, 0.04, and 0.008 ul were used to infect the culture of HeLa cells. Two to three days later, positive (green) cell colonies were counted using a fluorescence microscope.

#### Example 8 - Transfections.

10

Transfections of proviral clones were performed in HLtat cells using calcium phosphate DNA precipitation methods as described by the manufacturer (Stratagene). T7-based (PTM1) expression constructs were transfected using Lipofectin (BioRad) into rVT7 infected HeLa cells as described previously; (Wu et al., *J. Virol.* 1994,  
15 68:6161-6169). These methods were those recommended by the manufacturer of the Lipofectin reagent.

#### Example 9 - Western immunoblot analysis.

20

Virions and virus-like particles (VLPs) were concentrated from the supernatants of transfected or infected cells by ultracentrifugation through 20% cushions of sucrose (125,000 X g, 2 hrs., 4°C). Pellets and infected/transfected cells were solubilized in loading buffer [62.5 mM Tris-HCl (pH 6.8) 0.2% sodium dodecyl sulfate (SDS), 5% 2-mercaptoethanol, 10% glycerol], oiled and separated on 12.5% polyacrylamide gels  
25 containing SDS. Following electrophoresis, proteins were transferred to nitrocellulose (0.2 um; Schleicher & Schuell) by electroblotting, incubated for one hour at room temperature in blocking buffer (5% nonfat dry milk in phosphate buffered saline [PBS]) and then for two hours with the appropriate antibodies diluted in blocking buffer. Protein bound antibodies were detected with HRP-conjugated specific secondary  
30 antibodies using ECL methods according to the manufacturer's instructions (Amersham).

#### Example 10 - SN nuclease activity assay.

Cells and viral pellets were resuspended in nuclease lysis buffey (40 mM Tris-HCl, pH 6.8, 100 mM NaCl, 0.1% SDS, 1% Triton X-100) and clarified by low speed centrifugation (1000 X g, 10 min.). Tenfold dilutions were made in nuclease reaction cocktail buffer (100 mM Tris-HCl, pH 8.8, 10 mM CaCl<sub>2</sub>, 0.1% NP40) and boiled for 1 minute. 5 ul of each dilution was added to 14 ul of reaction cocktail buffer containing 500 ng of lambda phage DNA (HindIII fragments) and incubated at 37°C for 2 hours. Reaction products were electrophoresed on 0.8% agarose gels and DNA was visualized by ethidium bromide staining.

10

Example 11 - Expression of Vpr1- and Vpx2- SN and SN\* fusion proteins in mammalian cells.

Expression of Vpr1- and Vpx2- SN/SN\* fusion proteins in mammalian cells was assessed using the recombinant vaccinia virus-T7 system (rVT7). HeLa cells were grown to 75-80% confluency and transfected with the recombinant plasmids pTM-vpr, pTM-vpx, pTM-vpr1SN/SN\*, and pTMvpx2SN/SN\* (Figure 1). Twenty-four hours after transfection, cells were washed twice with PBS and lysed. Soluble proteins were separated by SDS-PAGE and subjected to immunoblot analysis. The results are shown in Figure 2. Transfection of pTM-vpr1SN and pTM-vpr1SN\* resulted in the expression of a 34 kDa fusion protein that was detectable using both anti-Vpr and anti-SN antibodies (A). Similarly, transfection of pTM-vpx2SN and pTMvpx2SN\* resulted in the expression of a 35 kDa fusion protein which was detected using anti-Vpx and anti-SN antibodies (B). Both fusion proteins were found to migrate slightly slower than expected, based on the combined molecular weights of Vpr1 (14.5 kDa) and SN (16 kDa) and Vpx2 (15 kDa) and SN, respectively. Transfection of pTM-vpr1 and pTM-vpx2 alone yielded appropriately sized wild-type Vpr and Vpx proteins. Anti-Vpr, anti-Vpx and anti-SN antibodies were not reactive with lysates of pTM1 transfected cells included as controls. Thus, both SN and SN\* fusion proteins can be expressed in mammalian cells.

30

Example 12 - Incorporation of Vpr1- and Vpr2- SN/SN\* fusion proteins into virus-like particles.

In vaccinia and baculovirus systems, the expression of HIV Gag is sufficient for assembly and extracellular release of VLPs. Vpr1 and Vpx2 can be efficiently incorporated into Gag particles without the expression of other viral gene products. To demonstrate that the Vpr1 and Vpx2 fusion proteins could be packaged into VLPs, recombinant plasmids were coexpressed with HIV-1 and HIV-2 Gag proteins in the rVT7 system. pTM-vpr1, pTM-vpr1SN and pTM-vpr1SN\* were transfected into HeLa cells alone and in combination with the HIV-1 Gag expression plasmid, pTM-gagl. Twenty-four hours after transfection, cell and VLP extracts were prepared and analyzed by immunoblot analysis (Figure 3A). Anti-Vpr antibody detected Vpr1, Vpr1SN and Vpr1SN\* in cell lysates (top panel) and in pelleted VLPs derived by coexpression with pTM-gagl (middle panel). In the absence of HIV-1Gag expression, Vpr1 and Vpr1SN were not detected in pellets of culture supernatants (middle panel). As expected VLPs also contained p55 Gag (bottom panel). Thus, Vpr1SN/SN\* fusion proteins were successfully packaged into VLPs.

To demonstrate that Vpx2SN was similarly capable of packaging into HIV-2 VLPs, pTM-vpx2, pTM-vpx2SN and pTM-vpx2SN\* were transfected into HeLa cells alone and in combination with the HIV-2 Gag expression plasmid, pTM-gag2. Western blots were prepared with lysates of cells and VLPs concentrated from culture supernatants by ultracentrifugation (Figure 3B). Anti-Vpx antibody detected Vpx2, Vpx2SN and Vpx2SN\* in cell lysates (top panel) and in VLPs derived by coexpression with pTM-gag2 (middle panel). Anti-Gag antibody detected p55 Gag in VLP pellets (bottom panel). Comparison of the relative protein signal intensities suggested that the Vpr1 and Vpx2- SN and SN\* fusion proteins were packaged into VLPs in amounts similar to wild-type Vpr1 and Vpx2 proteins. Sucrose gradient analysis of VLPs containing Vpr1SN and Vpx2SN demonstrated co-sedimentation of these fusion proteins with VLPs (data not shown).

The Gag C terminal region is required for incorporation of Vpr1 and Vpx2 into virions. However, packaging was found to be virus type-specific, that is, when expressed *in trans*, Vpx2 was only efficiently incorporated into HIV-2 virions and HIV-2 VLPs. Similarly, HIV-1 Vpr required interaction with the HIV-1 Gag precursor for incorporation into HIV-1 VLPs. To show that the association of Vpr1SN and Vpx2SN with VLPs was not mediated by the SN moiety, but was due to the Vpr and

Vpx specific packaging signals, pTM-vpr1SN and pTM-vpx2SN were cotransfected individually with either pTM-gag1 or pTM-gag2. For control, pTM-vpr1 and pTM-vpx2 were also transfected alone. Twenty-four hours later, lysates of cells and pelleted VLPs were examined by immunoblotting (Figure 4). While Vpr1SN was expressed in all cells (Figure 4A, top panel), it was only associated with VLPs derived from cells transfected with pTM-gag1. Similarly, Vpx2SN was detected in all pTM-vpx2 transfected cells (Figure 4B, top panel), but was only associated with VLPs derived by cotransfection with pTM-gag2 (Figure 4B, middle panel). HIV-1 and HIV-2 Gag monoclonal antibodies confirmed the presence of Gag precursor protein in each VLP pellet (Figure 4B, bottom panels). Thus, incorporation of Vpr1SN and Vpx2SN into VLPs requires interaction of the cognate Gag precursor protein, just like native Vpr1 and Vpx2.

While Vpr1SN and Vpx2SN fusion proteins clearly associated with VLPs (Figure 3), the question remained whether they would continue to do so in the presence of the native accessory proteins. The efficiency of Vpr1SN and Vpx2SN packaging was compared by competition analysis (Figure 5). pTM-vpr1SN and pTM-vpx2SN were cotransfected with pTM-gag1/pTM-vpr1 and pTM-gag2/pTM-vpx2, respectively, using ratios that ranged from 1:4 to 4:1 (Figure 5A and Figure 5B, left panels). For comparison, pTM-vpr1SN and pTM-vpr1 were transfected individually with pTM-gag1 (Figure 5A, middle and right panels respectively) and pTM-vpx2SN and pTM-vpx2 were transfected with pTM-gag2 (Figure 5B, middle and right panels respectively). VLPs were pelleted through sucrose cushions, lysed, separated by PAGE, blotted onto nitrocellulose and probed with anti-SN antibody. The results revealed the presence of both Vpr1 and Vpr1SN in VLPs when cotransfected into the same cells (Figure 5A, left panel). Similarly, coexpressed Vpx2 and Vpx2SN were also copackaged (Figure 5B, left panel). Comparison of the relative amounts of VLP-associated Vpr1SN and Vpx2SN when expressed in the presence and absence of the native protein, indicated that there were no significant packaging differences. Thus, Vpr1/Vpx2 fusion proteins can efficiently compete with wild-type proteins for virion incorporation.

Example 13 – Vpr1SN and Vpx2SN fusion proteins possess nuclease activity.

To demonstrate that virion associated SN fusion proteins were enzymatically active, VLPs concentrated by ultracentrifugation from culture supernatants of HeLa cells transfected with pTM-gag/pTM-vpr1SN and pTMgag2/pTM-vpx2SN were analyzed for nuclease activity using an *in vitro* DNA digestion assay. Prior to this analysis, immunoblotting confirmed the association of Vpr1SN and Vpx2SN with VLPs (data not shown). Figure 6 shows lambda phage DNA fragments in 0.8% agarose gels after incubation with dilutions of VLPs lysates that contained Vpr1- or Vpx2- SN fusion proteins. VLPs containing Vpr1SN\* and Vpx2SN\* were included as negative controls and dilutions of purified SN served as reference standards (Figure 6A). Both virion associated Vpr1SN (Figure 6B) and Vpx2SN (Figure 6C) fusion proteins exhibited nuclease activity as demonstrated by degradation of lambda phage DNA. Cell-associated Vpr1SN and Vpx2SN fusion proteins also possessed nuclease activity when analyzed in this system (data not shown). To control for SN specificity, this analysis was also conducted in buffers devoid of Ca<sup>++</sup> and under these conditions no SN activity was detected (data not shown). Thus, SN remains enzymatically active when expressed as a fusion protein and packaged into VLPs.

#### Example 14 - Incorporation of Vpx2SN fusion protein into HIV-2 virions.

Vpx is incorporated into HIV-2 virions when expressed *in trans*. To show that Vpx2 fusion proteins were similarly capable of packaging into wildtype HIV-2 virions, an expression plasmid (pLR2P) was constructed placing the vpx2SN and vpx2SN\* coding regions under control of HIV-2 LTR and RRE elements. The HIV-2 RRE was positioned downstream of the fusion genes to ensure mRNA stability and efficient translation (Figure 7A). To show that the fusion proteins could package when expressed *in trans*, HIV-2<sub>ST</sub> proviral DNA (PSXBI) was transfected alone and in combination with pLR2P-vpx2SN and pLR2P-vpx2SN\*. Forty-eight hours later, extracellular virus as pelleted from culture supernatants by ultracentrifugation through cushions of 20% sucrose and examined by immunoblot analysis (Figure 7B). Duplicate blots were probed using anti-Vpx (left), anti-SN (middle) and anti-Gag (right) antibodies. Anti-Vpx antibody detected the 15 kDa Vpx2 protein in all viral pellets. In virions derived by cotransfection of HIV-2<sub>ST</sub> with pLR2P-vpx2SN and pLR2P-vpx2SN\*, additional proteins of approximately 35 and 32 kDa were clearly visible.

The same two proteins were also apparent on a duplicate blot probed with anti-SN antibodies, indicating that they represented Vpx2SN fusion proteins (Figure 7B, middle panel). The predicted molecular weight of full-length Vpx2SN fusion protein is 33kDa. As native Vpx and SN run slightly slower than predicted, it is likely that the 35 kDa species represents the full-length Vpx2SN fusion protein. Anti-SN antibodies detected additional proteins of approximately 21 and 17 kDa (these proteins were more apparent after longer exposure). Since only the 35 kDa protein was detected in Gag derived VLPs, which lack Pol proteins (Figure 2), the smaller proteins represented cleavage products of Vpx2SN and Vpx2SN\* generated by the viral protease. Anti-Gag antibodies confirmed the analysis of approximately equivalent amounts of virions from each transfection.

To show packaging of Vpx2SN into HIV-2 virions, sucrose gradient analysis was performed. Extracellular virus collected from culture supernatants of HLtat cells forty-eight hours after cotransfection with pLR2P-vpx2SN and HIV-2<sub>ST</sub> was pelleted through cushions of 20% sucrose. Pellets were resuspended in PBS and then centrifuged for 18 hours over linear gradients of 20-60% sucrose. Fractions were collected and analyzed by immunoblotting (Figure 7C). Duplicate blots were probed separately with anti-SN (top) and anti-Gag (bottom) antibodies. Peak concentrations of both Vpx2SN and Gag were detected in fractions 8-11, demonstrating direct association and packaging of Vpx2SN into HIV-2 virions. These same sucrose fractions (8-11) were found to have densities between 1.16 and 1.17 g/ml, as determined by refractometric analysis (data not shown). Again, both the 35 kDa and 32 kDa forms of Vpx2SN were detected, providing further evidence for protease cleavage following packaging into virus particles.

Since HIV-2<sub>ST</sub> is defective in *vpr*, this may have affected the packaging of the Vpx2SN fusion protein. A second strain of HIV-2, termed HIV-2<sub>7312A</sub>, was analyzed which was cloned from short-term PBMC culture and contains open reading frames for all genes, including intact *vpr* and *vpx* genes (unpublished). A plasmid clone of HIV-2<sub>7312A</sub> proviral DNA (pJK) was transfected alone and in combination with pLR2P-vpx2SN into HLtat cells. For comparison, HIV-2<sub>ST</sub> was also co-transfected with pLR2P-vpx2SN. Progeny virus was concentrated by ultracentrifugation through sucrose cushions and examined by immunoblot analysis (Figure 7D). Duplicate blots

were probed with anti-Vpx (left) and anti-Gag (right) antibodies. The results revealed comparable levels of Vpx2SN incorporation into *vpr* competent virus (HIV-2<sub>7312A</sub>) compared with *vpr-defective* virus (HIV-2<sub>ST</sub>). Moreover, the 35 kDa and 32 kDa proteins were again detected in HIV-2<sub>7312A</sub> virions. Thus, efficient incorporation of the Vpx2SN protein into replication-competent wildtype HIV-2 was demonstrated, even in the presence of native Vpr and Vpx proteins.

Example 15 - Incorporation of Vpr1SN into HIV-1 virions.

Using the same LTR/RRE-based expression plasmid, it was also shown that Vpr1SN could package into HIV-1 virions by co-expression with HIV-1 provirus (as discussed above, the HIV-2 LTR can be transactivated by HIV-1 Tat and the HIV-2 RRE is sensitive to the HIV-1 Rev protein). Virions released into the culture medium 48 hours after transfection of HLTat cells with pNL4-3 (HIV-1) and pNL4-3-R- (HIV-1-R-) alone and in combination with pLR2P-vpr1SN were concentrated by ultracentrifugation and examined by immunoblot analysis (Figure 8). As observed in cotransfection experiments with HIV-2, anti-SN antibodies identified two major Vpr1SN fusion proteins of approximately 34 to 31 kDa. These proteins were not detected in virions produced by transfection of pNL4-3 and pNL4-e-R- alone. From expression in the rVT7 system, the full-length Vpr1SN fusion protein was expected to migrate at 34 kDa. Therefore, the 31 kDa protein likely represents a cleavage product. Anti-SN antibodies also detected a protein migrating at 17 kDa. Anti-Vpr antibody detected the 34 and 31 kDa proteins in virions derived from cotransfected cells. It is noteworthy that both the anti-Vpr and anti-SN antibodies detected the 31 kDa protein most strongly, and that anti-Vpr antibody did not detect the 17 kDa protein recognized by anti-SN antibody. These results also show that even in virions in which native Vpr protein was packaged, Vpr1SN was also incorporated in abundance. Gag monoclonal antibody detected similar amounts of Gag protein in all viral pellets and demonstrated processing of the p55 Gag precursor (Figure 8C).

To demonstrate more directly that cleavage of the Vpr1- and Vpx2-SN fusion proteins was mediated by the HIV protease, virus was concentrated from pNL4-3-R-/pLR2P-vpr1SN and pSXBI/pLR2P-vpx2SN transfected cells that were cultured in the presence of 1  $\mu$ M of the HIV protease inhibitor L-689,502 (provided by Dr. E. Emini,

Merck & Co. Inc.). As expected, immunoblot analysis of virions demonstrated substantially less processing of p55 Gag (Figure 9A). Similarly, virions produced in the presence of L-689,502 also contained greater amounts of the uncleaved species of Vpr1SN and Vpx2SN fusion proteins (Figure 9B). Taken together, these results demonstrate that Vpr1- and Vpx2-SN fusion proteins are subject to protease cleavage during or subsequent to virus assembly.

Example 16 – Vpr1-CAT and Vpr-2-CAT fusion protein incorporation into HIV virions.

10

To show that Vpx2 and Vpr1 could target additional proteins to the HIV particle, the entire 740 bp *CAT* gene was substituted for SN in the pLR2P-vpx2SN and pLR2P-vpr1SN vectors, generating pLR2P-vpr1CAT and pLR2P-vpx2CAT (Figure 10A). pNL4-3/pLR2P-vpr1CAT, pNL4-3-R-/pLR2P-vpr1CAT and pSXBI/pLR2P-vpx2CAT were co-transfected into HLtat cells. As controls, pNL4-3, pNL4-3-R- and pSXBI were transfected alone. Progeny virions, concentrated from culture supernatants, were analyzed by immunoblotting (Figure 10B and 10C). Using anti-Vpr antibodies, 40 kDa fusion proteins were detected in viral pellets derived by co-transfection of pLR2P-vpr1CAT with both pNL4-3 and pNL4-3-R- (Figure 10B). This size is consistent with the predicted molecular weight of the full-length Vpr1CAT fusion protein. In addition, anti-Vpr antibodies also detected a 17 kDa protein which did not correspond to the molecular weight of native Vpr1 protein (14.5 kDa in virions derived from cells transfected with pNL4-3). The same protein was recognized weakly with anti-CAT antibodies, suggesting a fusion protein cleavage product containing most Vpr sequence. Very similar results were obtained with virions derived from HLtat cells co-transfected with HIV-2<sub>ST</sub> and pLR2P-vpx2CAT, in which anti-Vpx antibody detected 41 and 15 kDa proteins (Figure 10C). These results demonstrate that Vpr1CAT and Vpx2CAT fusion proteins are packaged into virions. However, like in the case of SN fusion proteins, CAT fusion proteins were also cleaved by the HIV protease (the Vpx2CAT cleavage product is not visible because of co-migration with the native Vpx protein). CAT cleavage appeared less extensive, based on the intensity of the full-length CAT fusion protein on immunoblots.

30

Lysates of HIV-1 and HIV-2 viral particles were diluted 1:50 in 20 mM Tris-base and analyzed for CAT activity by the method of Allon, et al., *Nature*, 1979, 282:864-869. Figure 10D indicates that virions which contained Vpr1CAT and Vpx2CAT proteins possessed CAT activity. These results show the packaging of active Vpr1- and Vpx2- CAT fusion proteins.

Example 17 - Virion incorporated SN and CAT fusion proteins are enzymatically active.

The ability of Vpr1 and Vpx 2 to deliver functionally active proteins to the virus particle was further confirmed by sucrose gradient analysis. Virions derived from HLtat cells co-transfected with HIV-2<sub>ST</sub> and pLR2P-vpx2 were sedimented in linear gradients of 20-60% sucrose as described above. Fractions were collected and analyzed for viral Gag protein (Figure 11) and corresponding CAT activity (Figure 11B). Peak amounts of Gag protein were detected in fractions 6 and 7 (density 1.16 and 1.17, respectively). Similarly, peak amounts of acetylated chloramphenicol (Ac-cm) were also detected in fractions 6 and 7.

Whether virion associated SN fusion protein retained nuclease activity was also shown. HIV-1<sub>SG3</sub> virions containing Vpr1SN were analyzed after sedimentation in linear gradients of sucrose (Figure 11). Since the present invention demonstrated that protease cleavage of SN fusion proteins (Figures 7, 8 and 9) markedly reduced Vpr1SN nuclease activity (data not shown), these experiments were performed by culturing pSG3/pLR2P-vpr1SN co-transfected cells in the presence of L-689,502 as described above. Immunoblot analysis of sedimented virions revealed peak concentrations of Gag in fractions 6 and 7 and substantially reduced p55 processing (Figure 11C). Peak SN activity was associated with the fractions that contained the highest concentrations of virus (Figure 11D). These results thus document that virion incorporation *per se* does not abrogate the enzymatic activity of Vpr/Vpx fusion proteins, although cleavage by the viral protease may inactivate the fusion partners.

Example 18- Construction and design of a gag-pro (RT-IN minus) packaging plasmid.

Several different strategies have been used to express Gag-Pro. Placing Gag and Pro in the same reading frame leads to over expression of Pro and marked cell

toxicity. It is known that deletions within the RT and IN coding regions, including smaller deletion mutations, may cause marked defects in the expression levels of the Gag-Pro and Gag-Pol proteins, respectively (Ansari-Lari, M.A. et al., *Virology* 1995, 211:332-335; Ansari-Lari, M.A. et al., *J. Virol.* 1996, 70:3870-3875; Bukovsky, A. et al., *J. Virol.* 1996, 70:6820-6725; Engelman, A. et al., *J. Virol.* 1995, 69:2729-2736; Schnell, M.J. et al., *Cell Press* 1997, 90:849-857). Importantly, the viral particles produced under these circumstances are defective in proteolytic processing and are not infectious, even if RT and IN are provided *in trans* (Wu, X. et al., *J. Virol.* 1994, 68:6161-6169). The reduced levels of expression and virion associated Gag-Pol protein is apparently due to an effect on the frequency of Gag-Pol frame-shifting. Gag-Pol frame-shifting is not markedly affected when the translation of RT and IN is abrogated, which is distinct from deletions of viral DNA fragments. Virions which assemble Gag-Pro, when RT and IN protein synthesis is abrogated by a translational stop codon, mature and are infectious when RT and IN are provided *in trans* (Wu, X. et al., *J. Virol.* 1994, 68:6161-6169). Therefore, a Gag-Pro packaging plasmid of the present invention is preferably constructed by abrogating translation of sequence downstream of Pro (RT-IN). Other mutations in Gag and Pol would also function as part(s) of the transactivating packaging system if they did not cause major defects in particle assembly and infectivity. In addition to introducing a translational stop codon (TAA) at the first amino acid residue of RT, at least one additional "fatal" mutation is positioned within RT and IN (Fig. 12B). This mutation further decreases the likelihood of reestablishing a complete Gag-Pol coding region by genetic recombination between packaging (gag-pro) and enzymatic (vpr-RT-IN) plasmids. It is appreciated that the stop codon can be inserted within the gene sequence in a position other than at the first codon for the first amino acid residue of a protein and still be an effective measure to prevent infectivity. A stop codon generally inserted with the front half of the amino acid encoding nucleic acid residues is effective, although the stop codon is preferentially at the beginning of the translational sequence. A fatal mutation as used herein refers to a mutation within the gene sequence that renders the coded polypeptide sequence functionally ineffectual in performing the biological role of the wild protein.

The Gag-Pro expression plasmid (pCR-gag-pro) includes the CMV promoter and the HIV-2 Rev responsive element (RRE) (Fig. 12C). The RRE allows for the efficient expression of HIV proteins (including Gag, PR, RT, IN) that contain mRNA

inhibitory sequences. RT and IN are provided by transexpression with the pLR2P-vpr-RT-IN expression plasmid (Fig. 12C). This vector expresses the Vpr-RT-IN fusion protein which is incorporated into HIV-1 virions/vector *in trans*, and is proteolytically processed by the viral protease to generate functional forms of RT (p51 and p66) and IN (Wu, X. et al., *J. Virol.* 1994, 68:6161-6169). This earlier work shows that functional RT and IN can be provided separately (Vpr-RT and Vpr-IN) (Liu, H. et al., *J. Virol.* 1997, 71:7704-7710; Wu, X. et al., *J. Virol.* 1994, 68:6161-6169). Preferably, the Vpr component of the fusion protein contains a His71Arg substitution which knocks out the Vpr cell cycle arrest function.

#### Example 19 - Production of the trans-lentiviral vector.

4 ug each of pCR-gag-pro, pLR2P-vpr-RT-IN (enzymatic plasmid), pHR-CMV- $\beta$ -gal (marker gene transduction plasmid) and pCMV-VSV-G (env plasmid) were transfected into 293T cell line. 293T cells were used since they produce high titered stocks of HIV particles/vector and are exquisitely sensitive to transfection, including multiple plasmid transfections. As a control, in side-by-side experiments, the p $\Delta$ 8.2 packaging plasmid was also transfected with pHR-CMV- $\beta$ -gal and PCMV-VSV-G (Fig. 12B). The p $\Delta$ 8.2 plasmid is a lentivirus packaging vector obtained from Dr. D. Trono. The p $\Delta$ 8.2 produces high titered vector stocks upon transfection with pHR-CMV- $\beta$ -gal and PCMV-VSV-G (Naldini L. et al., *Science* 1996, 272:263-267; Zhang, J. et al., *Science* 1993, 259:234-238), (approximately  $1-5 \times 10^5$  infectious particles/ml supernatant, with a p24 antigen concentration of 150-800 ng/ml). Approximately 72 hours after transfection, the culture supernatants were harvested, clarified by low-speed centrifugation, filtered through a 0.45 micron filter, and analyzed for p24 antigen concentration by ELISA. To examine the titer of the trans-lentiviral vector, supernatant stocks of 25, 5, 1, and 0.2 ul were used to infect cultures of HeLa cells and IB3 cells. Two days later, the cells are stained with X-gal, and positive (blue) cells are counted using a light microscope. Table 3 shows the titer of trans-lentiviral vector. These results show that the trans-lentiviral vector can achieve titers as high as  $2 \times 10^5$ /ml, although its titer is consistently lower than that of lentiviral vector (2-5 fold less). For

direct examination of transduction in living cells the transduction plasmid was also constructed to contain the GFP gene/marker

(Fig. 12B and 12C). Stocks of trans-lentiviral and lentiviral vector were produced as described above and used to infect HeLa cells. Two days later the cells were examined

5 by fluorescence microscopy. Figures 13 and 14 show positive gene transduction with the trans-lenti and lentiviral vectors respectively.

Table 3

## Generation of Trans-Lentiviral Vector

10	Packaging Plasmid	RT-IN Plasmid	Titer (inf. units/ml X 10 <sup>-5</sup> )	
			HeLa	IB3
	pCMVΔR9	---	2.5 (+/-5.1)	1.2 (+/-2.7)
	PCMVAR9-SRT-IN	---	0	0
	pCMVΔR9-SRT-IN	Vpr-RT-IN	1.1 (+/-3.1)	0.8 (+/-2.5)

15

Example 20 - Concentration of Trans-lentiviral vector by ultracentrifugation.

To examine whether the trans-lentiviral vector was stable during the concentration by ultracentrifugation, the supernatant-trans-lentiviral vector was concentrated by ultracentrifugation (SW28, 23,000 rpm, 90 min., 4°C). As a control, supernatant-lentiviral vector was concentrated in parallel. The titers for both were determined both before and after concentration. Table 4 shows our results and indicates that the trans-lentiviral vector is stable during concentration by ultracentrifugation.

25

Table 4

## Concentration of Trans-Lentiviral Vector

30	Packaging Plasmid	RT-IN Plasmid	Titer (inf. units/ml X 10 <sup>-5</sup> )	
			HeLa	ID3
	pCMVΔR9	---	54	31
	pCMVΔR9-SRT-IN	Vpr-RT-IN	28	19

Example 21 - Trans-lentiviral vector for CFTR gene transduction.

Lentiviral-based vectors are attractive for use in the lung due to their ability to transduce non-divided cells. This unique characteristic may represent an important advantage of lentiviral vectors for gene therapy of CF. A translentiviral vector was used to deliver the CFTR gene into HeLa cells. The CFTR gene was cloned into the pHR transduction plasmid, using SmaI and XhoI sites (Figure 15). Trans-lentiviral and lentiviral (as control) vectors were generated by transfection as described above, and used to transduce HeLa cells grown on cover slips. Two days later the cells were examined by immunofluorescence microscopy, using both polyclonal (Figure 16) and monoclonal antibodies (Figure 17). The results show CFTR expression and localization of CFTR on the cell surface. Furthermore, the transduced HeLa cells examined by SPQ (halide-sensitive fluorophore) showed restored CFTR function (Figure 18).

The present invention demonstrated the capability of HIV-1 Vpr and HIV-2 Vpx to direct the packaging of foreign proteins into HIV virions when expressed as heterologous fusion molecules. The *trans* complementation experiments with HIV proviral DNA revealed that Vpr1 and Vpx2 fusion proteins were also incorporated into replication-competent viruses. Moreover, packaging of the fusion proteins in the presence of wild-type Vpx and/or Vpr proteins (Figures 16 and 17) indicated that the viral signals mediating their packaging were not obstructed by the foreign components of the fusion molecules. Likewise, virion-associated SN and CAT fusion proteins remained enzymatically active.

Based on the immunoblot analysis of VLPs and virions, the present invention illustrates that both virion associated CAT and SN/SN\* are susceptible to cleavage by the viral protease. There appears to be at least one cleavage site in CAT and two cleavage sites in the SN/SN\* proteins. Based on calculated molecular weights of the major SN/SN\* cleavage products, it appears that SN and SN\* are cleaved, one site near their C termini and once near the fusion protein junctions. Since the fusion protein junctions of Vpr1SN and Vpx2SN are not identical it is also possible that these regions differ with respect to their susceptibility to the viral protease. Although Vpx2SN/SN\* were processed to a lesser extent than Vpr1SN (Figures 7 and 8), the major cleavage sites appear to be conserved. There is no doubt that both the HIV-1 and HIV-2

proteases recognize processing sites in the fusion partners and that there is sufficient physical contact to enable cleavage. This is evidenced both by the reduction of cleavage product intensities on immunoblots as well as by an increased enzymatic activity in the presence of an HIV protease inhibitor.

5           The demonstration that Vpr1 and Vpx2 fusion proteins are capable of associating with both VLPs and virions facilitates studies on these accessory proteins and on HIV assembly in general. The approach of generating deletion mutants to study protein structure/function relationships is often of limited value since this can reduce protein stability or change the three-dimensional structure of the protein. In the case of  
10   Vpr, a single amino acid substitution at residue 76 has been shown to destabilize its expression in infected cells. Studies have indicated that deletion mutations in *vpr* and *vpx* result in premature degradation of the proteins following expression. Fusion of Vpr and Vpx mutant proteins with, e.g., SN or CAT as demonstrated by the present invention, increase stability.

15           The successful packaging of Vpr1Vpx2SN fusion proteins into virions indicates their use for accessory protein targeted viral inactivation. The present invention demonstrates that Vpr and Vpx may serve as vehicles for specific targeting of virus inhibitory molecules, including SN. In contrast to HIV Gag, Vpr and Vpx are small proteins that can be manipulated relatively easily without altering virus  
20   replication and thus may represent vehicles with considerable versatility for application to such an antiviral strategy.

Example 22 - Incorporation of RT *in trans* into a lentiviridis independent of HIV accessory proteins.

25           The HIV accessory proteins, Vpr and Vpx, are incorporated into virions through specific interactions with the p6 portion of the Pr55<sup>Gag</sup> precursor protein (Kappes et al., 1993; Kondo et al., *J. Virol.* 1995, 69:2759-2764; Lu et al., *J. Virol.* 1995, 69:6873-6879; Paxton et al., *J. Virol.* 1993, 67:72297237; Wu et al., *J. Virol.* 1994, 68:6161-  
30   6169). Similarly, it has been demonstrated that Vpr and Vpx fusion proteins (Vpr- and Vpx- SN and CAT) are incorporated into virions through interactions with p6<sup>Gag</sup>, similar to that of the wild-type Vpr and Vpx proteins (Wu et al., *J. Virol.* 1995, 69:3389-3398). To analyze the contribution of Vpr for incorporation of the Vpr-RT

fusion protein into virions, an HIV-1 proviral clone mutated in p6<sup>Gag</sup> and PR (designated pNL43-Δ p6<sup>Gag</sup>, provided by Dr. Mingjun Huang) was cotransfected with pLR2P-vprRT into 293T cells. This mutant contains a TAA translational stop codon at the first amino acid residue position of p6<sup>Gag</sup>. This abrogated the Gag sequences that are required for Vpr virion incorporation. The pNL43-Δ p6<sup>Gag</sup> clone also contains a mutation (D25N) in the active site of PR, which enhances the release of the p6<sup>Gag</sup> mutant virus from the cell surface membrane (Gottlinger et al. 1991; Huang et al. 1995). As a control, the HIV-1 PR mutant PM3 (Kohl et al. 1988), derived from the same pNL4-3 parental clone, was also included for analysis. Progeny virions, purified from pNL43-Δ p6<sup>Gag</sup> transfected cell cultures, contained detectable amounts of RT protein (labeled as Vpr-p66), albeit in lesser amounts compared with virions derived from PM3 (Figure 19). Analysis of cell lysates confirmed expression, and compared with PM3, the accumulation of Vpr-RT in pLR2P-vprRT/pNL43-Δ p6<sup>G</sup>, cotransfected cells. Vpr<sup>S</sup>-RT was included as an additional control and was shown to incorporate Vpr efficiently into PM3 virions but not into those derived by coexpression with pNL43-Δ p6<sup>Gag</sup>. Wildtype Vpr protein was also absent from Δ p6<sup>Gag</sup> virions. Approximately equal amounts of Gag protein was detected in the different virus pellets, confirming that similar amounts of the different virions were compared in the quantitation. These results show that RT protein can be incorporated into virions independently of Vpr-p6 mediated interaction. These data also indicate that expression of RT (and IN by inference) *in trans*, independently of Gag-Pol, is sufficient for its incorporation and function.

Example 23 - Expression of RT *in trans* in a lentivirus vector independent of HIV accessory.

It has been demonstrated that functional RT can be incorporated into HIV-1 virions by its expression *in trans*, even without fusion to Vpr (Example 19). To determine if RT expressed *in trans* can package into lentiviral vector and support the transduction of a marker gene, RT was ligated into the pLR2P expression plasmid under control of the HIV LTR and RRE, generating the pLR2P-RT expression plasmid. The pLR2P-RT, pHR-CMV-VSV-G, pHRCMV-β-gal, and pΔ8.2-RT<sup>D185N</sup> was

transfected together into 293T cells. The pΔ8.2-RT<sup>D185N</sup> plasmid contains a point mutation in RT at amino acid residue position 185 (D185N), which abolishes polymerase activity and destroys its ability to support gene transduction. As a control Vpr-RT (pLR2P-vpr-RT) was substituted for pLR2P-RT in a parallel experiment. As  
5 another control neither RT or Vpr-RT were provided. Virions generated by transfection were used to infect HeLa cells. Two days later, transduction positive cells were counted. Figure 20 shows that both Vpr-RT and RT support vector transduction when provided *in trans*. The vector titer was reduced by about 10 fold when RT was provided without fusion with Vpr. These results demonstrate that enzymatic function  
10 (RT and IN) can be provided *in trans*, independently of Gag-Pol.

The present invention demonstrated that Vpr and Vpx can serve as vehicles to deliver functionally active enzymes to the HIV virion, including those that may exert an antiviral activity such as SN. The present invention has demonstrated that the concept of accessory protein targeted virus inactivation is feasible.

15 Any patents or publications mentioned in this specification are indicative of the levels of those skilled in the art to which the invention pertains. These patents and publications are herein incorporated by reference to the same extent as if each individual publication was specifically and individually indicated to be incorporated by reference.

20 One skilled in the art will readily appreciate that the present invention is well adapted to carry out the objects and obtain the ends and advantages mentioned, as well as those inherent therein. The present examples along with the methods, procedures, treatments, molecules, and specific compounds described herein are presently representative of preferred embodiments, are exemplary, and are not intended as  
25 limitations on the scope of the invention. Changes therein and other uses will occur to those skilled in the art which are encompassed within the spirit of the invention as defined by the scope of the claims.

## We Claim:

1. A translenti viral vector system comprising:  
at least a first nucleic acid segment encoding at least one fusion protein  
5 comprising at least a functional portion of a Gag protein and a functional portion of  
reverse transcriptase and/or integrase, said segment capable of expression in a  
mammalian cell *in trans* to viral nucleic acid sequences present in said cell, said  
functional portion of Gag further capable of providing for the incorporation of said  
reverse transcriptase and/or said integrase into a translenti viral particle produced  
10 within said cell.
2. A translenti viral vector system of claim 1 further comprising at least a second  
nucleic acid segment encoding at least a functional portion of Gag and a functional  
portion of protease, said segment provided on the same or a different nucleic acid  
15 strand than said first segment, said segment capable of expression in a mammalian cell  
*in trans* to viral nucleic acid sequences present in said cell, said functional portion of  
said Gag and protease providing for packaging of RNA, particle formation, and  
proteolytic cleavage.
- 20 3. A translenti viral vector system according to claim 2 further comprising at least  
a third nucleic acid segment comprising nucleic acid sequence encoding an envelope  
gene of a virus, said segment provided on a different or same nucleic acid strand as said  
first and said second nucleic acid segments.
- 25 4. A translenti viral vector system according to claim 3 further comprising at least  
a fourth nucleic acid segment comprising a nucleic acid sequence encoding at least one  
protein of interest, said segment further comprising cis acting nucleic acid sequences  
for packaging, reverse transcription and integration, said segment further comprising  
sufficient long terminal repeat nucleic acid sequences capable of supporting integration  
30 of a reverse transcribed DNA product of said segment into nucleic acid sequences of a  
host genome.

5. A translenti viral vector system according to claim 4 further comprising a nucleic acid promotor sequence and nucleic acid sequences for facilitating transduction of said fourth segment into a cell.
- 5 6. A translenti viral vector of claim 5 wherein said nucleic acid sequences for facilitating transduction are selected from the group consisting of PPT-CTS and WPRE.
7. A translenti viral vector system according to any of claims 1, 2, 3, or 4 wherein said functional portions of said Gag protein and/or said protease are derived from  
10 retrovirus Gag and protease sequences.
8. A translenti viral vector system according to claim 7 wherein said retrovirus is selected from the group consisting of HIV, SIV, EIAV, BIV, FIV, and MLV.
- 15 9. A translenti viral vector system comprising:  
(a) at least a first nucleic acid segment encoding at least one fusion protein comprising at least a functional portion of a Gag protein and a functional portion of reverse transcriptase and/or integrase, said segment capable of expression in a mammalian cell *in trans* to viral nucleic acid sequences present in said cell, said  
20 functional portion of Gag further capable of providing for the incorporation of said reverse transcriptase and/or said integrase into a translenti viral particle produced within said cell; and  
(b) at least a second nucleic acid segment encoding at least a functional portion of Gag and a functional portion of protease, said segment provided on the same  
25 or a different nucleic acid strand than said first segment, said segment capable of expression in a mammalian cell *in trans* to viral nucleic acid sequences present in said cell, said functional portion of said Gag and protease providing for packaging of RNA, particle formation, and proteolytic cleavage.
- 30 10. A translenti viral vector system according to claim 9 further comprising at least a third nucleic acid segment comprising nucleic acid sequence encoding an envelope gene of a virus, said segment provided on a different or same nucleic acid strand as said first and said second nucleic acid segments.

11. A translenti viral vector system according to claim 10 further comprising at least a fourth nucleic acid segment comprising a nucleic acid sequence encoding at least one protein of interest, said segment further comprising cis acting nucleic acid sequences for packaging, reverse transcription and integration, said segment further comprising sufficient long terminal repeat nucleic acid sequences capable of supporting integration of a reverse transcribed DNA product of said segment into nucleic acid sequences of a host genome.
12. A translenti viral vector system according to claim 11 further comprising a nucleic acid promotor sequence and nucleic acid sequences for facilitating transduction of said fourth segment into a cell.
13. A translenti viral vector of claim 12 wherein said nucleic acid sequences for facilitating transduction are selected from the group consisting of PPT-CTS and WPRE.
14. A translenti viral vector system according to any of claims 9, 10, or 11 wherein said functional portions of said Gag protein and/or said protease are derived from retrovirus Gag and protease sequences.
15. A translenti viral vector system according to claim 14 wherein said retrovirus is selected from the group consisting of HIV, SIV, EIAV, BIV, FIV, and MLV.
16. A translenti viral vector system comprising:
- (a) at least a first nucleic acid segment encoding at least one fusion protein comprising at least a functional portion of a Gag protein and a functional portion of reverse transcriptase and/or integrase, said segment capable of expression in a mammalian cell *in trans* to viral nucleic acid sequences present in said cell, said functional portion of Gag further capable of providing for the incorporation of said reverse transcriptase and/or said integrase into a translenti viral particle produced within said cell;
- (b) at least a second nucleic acid segment encoding at least a functional portion of Gag and a functional portion of protease, said segment provided on the same

or a different nucleic acid strand than said first segment, said segment capable of expression in a mammalian cell *in trans* to viral nucleic acid sequences present in said cell, said functional portion of said Gag and protease providing for packaging of RNA, particle formation, and proteolytic cleavage; and

- 5           (c)     at least a third nucleic acid segment comprising nucleic acid sequence encoding an envelope gene of a virus, said segment provided on a different or same nucleic acid strand as said first and said second nucleic acid segments.

- 10       17.     A translenti viral vector system according to claim 16 further comprising at least a fourth nucleic acid segment comprising a nucleic acid sequence encoding at least one protein of interest, said segment further comprising cis acting nucleic acid sequences for packaging, reverse transcription and integration, said segment further comprising sufficient long terminal repeat nucleic acid sequences capable of supporting integration of a reverse transcribed DNA product of said segment into nucleic acid  
15     sequences of a host genome.

18.     A translenti viral vector system according to claim 17 further comprising a nucleic acid promotor sequence and nucleic acid sequences for facilitating transduction of said fourth segment into a cell.

- 20       19.     A translenti viral vector of claim 18 wherein said nucleic acid sequences for facilitating transduction are selected from the group consisting of PPT-CTS and WPRE.

20.     A translenti viral vector system according to any of claims 16 or 17 wherein  
25     said functional portions of said Gag protein and/or said protease are derived from retrovirus Gag and protease sequences.

21.     A translenti viral vector system according to claim 20 wherein said retrovirus is selected from the group consisting of HIV, SIV, ELAV, BIV, FIV, and MLV.

30

22.     A translenti viral vector system comprising:

- (a)     at least a first nucleic acid segment encoding at least one fusion protein comprising at least a functional portion of a Gag protein and a functional portion of

- reverse transcriptase and/or integrase, said segment capable of expression in a mammalian cell *in trans* to viral nucleic acid sequences present in said cell, said functional portion of Gag further capable of providing for the incorporation of said reverse transcriptase and/or said integrase into a translenti viral particle produced within said cell;
- (b) at least a second nucleic acid segment encoding at least a functional portion of Gag and a functional portion of protease, said segment provided on the same or a different nucleic acid strand than said first segment, said segment capable of expression in a mammalian cell *in trans* to viral nucleic acid sequences present in said cell, said functional portion of said Gag and protease providing for packaging of RNA, particle formation, and proteolytic cleavage;
- (c) at least a third nucleic acid segment comprising nucleic acid sequence encoding an envelope gene of a virus, said segment provided on a different or same nucleic acid strand as said first and said second nucleic acid segments; and
- (d) at least a fourth nucleic acid segment comprising a nucleic acid sequence encoding at least one protein of interest, said segment further comprising *cis* acting nucleic acid sequences for packaging, reverse transcription and integration, said segment further comprising sufficient long terminal repeat nucleic acid sequences capable of supporting integration of a reverse transcribed DNA product of said segment into nucleic acid sequences of a host genome.
23. A translenti viral vector system according to claim 22 further comprising with respect to (d) of claim 22 a nucleic acid promotor sequence and nucleic acid sequences for facilitating transduction of said fourth segment into a cell.
24. A translenti viral vector of claim 23 wherein said nucleic acid sequences for facilitating transduction are selected from the group consisting of PPT-CTS and WPRE.
25. A translenti viral vector system according to claim 22 wherein said functional portions of said Gag protein and/or said protease are derived from retrovirus Gag and protease sequences.

26. A transenti viral vector system according to claim 25 wherein said retrovirus is selected from the group consisting of HIV, SIV, EIAV, BIV, FIV, and MLV.
27. A transenti viral vector system according to any of claims 1, 9, 16, or 22  
5 wherein said fusion protein is capable of incorporation into a retrovirus virion, virion-like particle, or transenti vector particle when said protein is expressed *in trans* with respect to at least viral assembly and packaging nucleic acids.
28. A transenti viral vector system according to any of claims 1, 9, 16 or 22  
10 wherein said nucleic acid segment of (a) further comprises rev nucleic acid sequence encoding an expressable rev protein.
29. A transenti viral vector system according to any of claims 1, 9, 16 or 22  
15 capable of reducing infectivity of HIV-1 or HIV-2, comprising an effective amount of said vector in association with a pharmaceutically acceptable carrier.
30. A transenti viral vector system according to any of claims 4, 11, 17, or 22 further comprising a nucleic acid segment provided on the same or different nucleic acid strand as said fourth segment comprising a gene encoding a marker protein, said  
20 gene selected from the group consisting of  $\beta$ -gal, fluorescence proteins, and luciferase.
31. A transenti viral vector system according to any of claims 4, 11, 17, or 22 wherein said sequence encoding said protein of interest is provided on said fourth segment, said encoded protein selected from the group consisting of viral inhibitory  
25 protein, and therapeutic proteins.
32. A transenti viral vector system according to any of claims 1, 9, 16 or 22 further comprising a nucleic acid segment provided on the same or different nucleic acid strand as (a), comprising a gene encoding an antigen protein derived from a viral gene  
30 selected from the group consisting of gag, envelope, nef, and vif.

33. A translenti viral vector system according to any of claims 4, 11, 17, or 22 wherein said encoded protein of interest is a bacterial resistance protein selected from the group consisting of neomycin, hygromycin, and puromycin.
- 5 34. A translenti viral vector system according to any of claims 1, 4, 9, 11, 16, 17, or 22 further comprising promoters operatively linked to at least one of said first, second, third or fourth nucleic acid segments, said promoters comprising a nucleic acid sequence selected from the group consisting of HIV promoters, non-HIV promoters, constitutive promoters, and inducible promoters.
- 10 35. A translenti viral vector system according to any of claims 4, 11, 17, or 22 further comprising a poly A signal operatively linked to at least one of said first, second, third or fourth nucleic acid segments, said poly A selected from the group consisting of non HIV poly A, SV40 poly A, and non-lentiviral poly A.
- 15 36. A method for generating a translenti viral vector system comprising:
- (a) providing at least a first nucleic acid segment encoding at least one fusion protein comprising at least a functional portion of a Gag protein and a functional portion of reverse transcriptase and/or integrase, said segment capable of expression in
- 20 a mammalian cell *in trans* to viral nucleic acid sequences present in said cell, said functional portion of Gag further capable of providing for the incorporation of said reverse transcriptase and/or said integrase into a translenti viral particle produced within said cell;
- (b) providing at least a second nucleic acid segment encoding at least a
- 25 functional portion of Gag and a functional portion of protease, said segment provided on the same or a different nucleic acid strand than said first segment, said segment capable of expression in a mammalian cell *in trans* to viral nucleic acid sequences present in said cell, said functional portion of said Gag and protease providing for packaging of RNA, particle formation, and proteolytic cleavage;
- 30 (c) providing at least a third nucleic acid segment comprising nucleic acid sequence encoding an envelope gene of a virus, said segment provided on a different or same nucleic acid strand as said first and said second nucleic acid segments;

(d) contacting said nucleic acids of (a), (b), and (c) with a mammalian cell, said cell becoming transfected with said nucleic acids; and

(e) producing viral particles from said cell, said particles containing said fusion protein.

5

37. A method according to claim 36 further comprising providing at least a fourth nucleic acid segment comprising a nucleic acid sequence encoding at least one protein of interest, said segment further comprising cis acting nucleic acid sequences for packaging, reverse transcription and integration, said segment further comprising  
10 sufficient long terminal repeat nucleic acid sequences capable of supporting integration of a reverse transcribed DNA product of said segment into nucleic acid sequences of a host genome.

38. A method according to claim 37 wherein said fourth segment further comprises  
15 a nucleic acid promotor sequence and nucleic acid sequences for facilitating transduction of said fourth segment into a cell.

39. A method according to claim 38 wherein said nucleic acid sequences for facilitating transduction are selected from the group consisting of PPT-CTS and WPRE.

20

40. A method for generating a transenti viral vector system comprising:

(a) providing at least a first nucleic acid segment encoding at least one fusion protein comprising at least a functional portion of a Gag protein and a functional portion of reverse transcriptase and/or integrase, said segment capable of expression in  
25 a mammalian cell *in trans* to viral nucleic acid sequences present in said cell, said functional portion of Gag further capable of providing for the incorporation of said reverse transcriptase and/or said integrase into a transenti viral particle produced within said cell;

(b) providing at least a second nucleic acid segment encoding at least a  
30 functional portion of Gag and a functional portion of protease, said segment provided on the same or a different nucleic acid strand than said first segment, said segment capable of expression in a mammalian cell *in trans* to viral nucleic acid sequences

present in said cell, said functional portion of said Gag and protease providing for packaging of RNA, particle formation, and proteolytic cleavage;

(c) providing at least a third nucleic acid segment comprising a nucleic acid sequence encoding at least one protein of interest, said segment further comprising cis acting nucleic acid sequences for packaging, reverse transcription and integration, said  
5 segment further comprising sufficient long terminal repeat nucleic acid sequences capable of supporting integration of a reverse transcribed DNA product of said segment into nucleic acid sequences of a host genome;

(d) contacting said nucleic acids of (a), (b), and (c) with a mammalian cell,  
10 said cell becoming transfected with said nucleic acids; and

(e) producing viral particles from said cell, said particles containing said fusion protein.

41. A method according to claim 40 further comprising providing at least a fourth  
15 nucleic acid segment comprising nucleic acid sequence encoding an envelope gene of a virus, said segment provided on a different or same nucleic acid strand as said first and said second nucleic acid segments.

42. A method according to claim 40 wherein said third segment further comprises a  
20 nucleic acid promotor sequence and nucleic acid sequences for facilitating transduction of said fourth segment into a cell.

43. A method according to claim 42 wherein said nucleic acid sequences for  
facilitating transduction are selected from the group consisting of PPT-CTS and WPRE.

25

44. A method for generating a transenti viral vector system comprising:

(a) providing at least a first nucleic acid segment encoding at least one fusion protein comprising at least a functional portion of a Gag protein and a functional portion of reverse transcriptase and/or integrase, said segment capable of expression in  
30 a mammalian cell *in trans* to viral nucleic acid sequences present in said cell, said functional portion of Gag further capable of providing for the incorporation of said reverse transcriptase and/or said integrase into a transenti viral particle produced within said cell;

- (b) providing at least a second nucleic acid segment encoding at least a functional portion of Gag and a functional portion of protease, said segment provided on the same or a different nucleic acid strand than said first segment, said segment capable of expression in a mammalian cell *in trans* to viral nucleic acid sequences present in said cell, said functional portion of said Gag and protease providing for packaging of RNA, particle formation, and proteolytic cleavage;
- (c) providing at least a third nucleic acid segment comprising nucleic acid sequence encoding an envelope gene of a virus, said segment provided on a different or same nucleic acid strand as said first and said second nucleic acid segments;
- (d) providing at least a fourth nucleic acid segment comprising a nucleic acid sequence encoding at least one protein of interest, said segment further comprising cis acting nucleic acid sequences for packaging, reverse transcription and integration, said segment further comprising sufficient long terminal repeat nucleic acid sequences capable of supporting integration of a reverse transcribed DNA product of said segment into nucleic acid sequences of a host genome;
- (e) contacting said nucleic acids of (a), (b), (c) and (d) with a mammalian cell, said cell becoming transfected with said nucleic acids; and
- (f) producing viral particles from said cell, said particles containing said fusion protein.

20

45. A method according to claim 44 wherein said fourth segment further comprises a nucleic acid promotor sequence and nucleic acid sequences for facilitating transduction of said fourth segment into a cell.

25

46. A method according to claim 45 wherein said nucleic acid sequences for facilitating transduction are selected from the group consisting of PPT-CTS and WPRE.

47. A method according to claims 36 or 40 wherein said nucleic acid segment of (a) further encodes an rev protein.

30

48. A method of claims 37, 40, or 44 capable of reducing infectivity of HIV-1 or HIV-2, comprising providing an effective amount of said vector in association with a pharmaceutically acceptable carrier.

49. A method of claims 37, 40, or 44 further comprising a nucleic acid segment provided on said fourth segment, comprising a nucleic acid sequence encoding a marker protein, said marker protein selected from the group consisting of  $\beta$ -gal, fluorescence proteins, and luciferase.
50. A method of claims 37, 40, or 44 wherein said fourth nucleic acid segment encodes a protein of interest selected from the group consisting of viral inhibitory protein, and therapeutic proteins.
51. A method of claims 37, 40, or 44 wherein said fourth nucleic acid segment encodes at least one drug resistant protein selected from the group consisting of neomycin, hygromycin, and puromycin.
52. A method of claims 37, 40, or 44 further comprising providing a promoter operatively linked to at least one of said first and second nucleic acid segments, said promoter comprising a nucleic acid sequence selected from the group consisting of HIV promoters, non-HIV promoters, constitutive promoters, and inducible promoters.
53. A method of claims 37, 40, or 44 further comprising providing a poly A signal operatively linked to at least one of said first, second, third, or fourth nucleic acid segments, said poly A selected from the group consisting of non HIV poly A, SV40 poly A, and non-lentiviral poly A.

## INTERNATIONAL SEARCH REPORT

International application No.  
PCT/US00/34021

## A. CLASSIFICATION OF SUBJECT MATTER

IPC(7) : C12N 15/63

US CL : 435/320.1

According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 435/320.1

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched  
none

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

Please See Extra Sheet.

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	HUANG et al. p6Gag is required for particle production from full-length Human Immunodeficiency Virus Type 1 molecular clones expressing protease. Journal of Virology. November 1995, Vol. 69, No. 11, pages 6810-6818, see entire document.	1-53
A	SCHUMANN et al. Therapeutic Effect of Gag-Nuclease Fusion Protein on Retrovirus-Infected Cell Cultures. Journal of Virology. July 1996, Vol. 70, No. 7, pages 4329-4337, see entire document.	1-53

☐ Further documents are listed in the continuation of Box C. ☐ See patent family annex.

* Special categories of cited documents:	*T* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
*A* document defining the general state of the art which is not considered to be of particular relevance	*X* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
*E* earlier document published on or after the international filing date	*Y* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
*L* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	*A* document member of the same patent family
*O* document referring to an oral disclosure, use, exhibition or other means	
*P* document published prior to the international filing date but later than the priority date claimed	

Date of the actual completion of the international search

06 FEBRUARY 2001

Date of mailing of the international search report

23 APR 2001

Name and mailing address of the ISA/US  
Commissioner of Patents and Trademarks  
Box PCT  
Washington, D.C. 20231
